It would appear, from this brief summary of the discussion, that while most of the speakers were agreed in thinking that more should be done for the provinces, the division between them was as to whether it should be done by grants of money or by increasing the loan system and extending it to the National Gallery and the British Museum. Now in regard to grants of public money to provincial towns for art museums, we must say that as a general rule (to which there may certainly be exceptional cases) we are disposed to think that the balance of arguments is against the use of public money in supplying local needs of this kind, strongly as we have for years urged the importance of establishing museums and galleries of art in our large provincial towns. We have already noticed the question raised by one member, "Where is it to stop?" and to that there is no satisfactory reply. It would hardly be possible to draw any line between one provincial town and another in this respect; subsidise an art museum for one, and it will be a standing grievance with every other town if it is not treated in the same way. Thus a large expenditure would be inevitable; and we do not see that a large expenditure of public money for such a purpose is reasonable except for what is of value to the nation at large, *i.e.*, for central and national institutions. But there is another consideration following on this, which Mr. Magniac half hinted at in his speech. Persons busied in acquiring objects of art always, he said, hated each other as rival collectors, and all the provincial towns would be placed in this invidious position. This might be got over by the suggestion of Mr. Collings, that the purchases should be authorised by South Kensington; but that does not dispose of the whole difficulty. It must be remembered that, after all, the amount of objects of art worth purchasing and keeping in a collection is not unlimited, especially if we take out the immense number which are never likely to be offered for public sale. The Government might give provincial bodies money with which to purchase objects of art and archæology, but it cannot do anything to enlarge the number of purchasable works of art that are worth giving money for. If the loan system were extended, however, a considerable number of objects might profitably be added, at public cost, to a collection which would then be shown in different places successively, and would become of more than merely local interest; and certainly the temporary possession of first-rate works is far more valuable and useful than the permanent possession of works of less value and excellence.

We by no means think, however, that the circulation system should be applied wholesale, or nearly so, to the majority of objects in the central museums of art. In the first place, there is great danger of loss or damage in sending such things from one place to another. In the case of the British Museum, for instance, we would on no account allow of the circulation of the more rare and valuable antiquities, such as, once lost, are lost for ever. Things of lesser value, or of which there were duplicate specimens, might be lent, and the system of making casts and *fac-similes* might be carried still further than it is already at South Kensington. But when people talk of sending things of this kind about the country from one place to another, they do not remember that, besides the risk of damage, the visitors to the Central National Museum (many from the provinces and distant parts of the world) have a right to expect to find that exhibition complete in all essentials, and not find it shorn of some of its chief specimens. In short, a national art museum is an institution which ought to be kept up in preference to local museums, and should naturally and rightly have the first consideration. Mr. Mundella observed, we have no doubt with truth, in replying to some of these suggestions, that there were already not unfrequent complaints from visitors to South Kensington who found that some of the things they had specially come to study had "gone into the country."

With regard to the far larger view suggested by Mr. Magniac, that the whole of the great national museums should be under one responsible head, and should be grouped in regard to the relation of their subjects to one another, while it would be unquestionably an immense task to accomplish, it would certainly be worth doing if it could be done without rendering a great portion of the contents of the museums inaccessible for a long time, and without rearranging and almost rebuilding, or largely adding to, the buildings containing them. But general re-grouping would, we fear, entail all this. The union of the whole under one Government Minister is quite possible, and would probably be of much benefit, more especially, as we venture to think, in breaking through some of the red tape of the British Museum, and compelling the authorities to do more to make the Museum, or some parts of it, generally useful. The state of mind habitual to British Museum Trustees and officials is significantly indicated in Sir John Lubbock's remark in the debate in question, in reply to a suggestion that the British Museum ought to have applied for Parliamentary powers to place some parts of their collection (such as the contents of the Print Room), where they would be of more general use to art students than where they are, and also for powers to lend works generally. Whereunto Sir John Lubbock, speaking, we presume, as a trustee of the British Museum, asks indignantly how it is to be expected that they are to ask for powers to alienate some of their greatest treasures? That is just a specimen of the singular illusion that some of the British Museum officials seem to labour under, that the British Museum is an institution existing for their particular honour and glory, and only for the public in a secondary and in a kind of "on sufferance" fashion. It is really as well that both trustees and officials should be reminded that the British Museum exists for the public, and that if it were proved that any part of its contents would be of more public utility elsewhere, their first duty would be to promote the change, not to oppose it as if the objects were property of their own, of which some one was seeking to deprive them.

Exhibition in Bolton.—The Earl of Bradford has consented to open the Fine Art Exhibition, in aid of the funds of the new infirmary at Bolton, on the 5th of September next. The infirmary building has recently been erected at a cost of 25,000*l.*, and is well adapted for the purposes of an exhibition of paintings and works of art. The Exhibition Committee have already been successful in obtaining the loan of a large number of very important and choice works of art, including more than forty pieces of sculpture, and a collection of bronzes, art pottery, and ancient armour.

MONUMENTS AND LOCAL MEMORIES.

The best locality for a monument, using the word in its primary acceptation of an architectural memorial of the dead, is a question that has been forced on our consideration by a recent loss to the world of letters. It is consistent with the simplicity of the character of Mr. Carlyle that he should have wished his remains to be laid to rest, near those of his wife, in the country churchyard of St. Fechan, in Ecclefechan. To his name there is no one who would have denied the right of inscription on the walls of Westminster Abbey. It remains, however, for consideration (if we are, indeed, justified in looking forward to a long and brilliant succession of great Englishmen) whether, even in exceptional cases such as his, the erection of a tablet should not be allowed to supersede the digging of a grave within the precincts of the Abbey. With the change that has come over public feeling (as well as public opinion) as to the evil practice of intramural interment, each applicant for a resting-place beneath the vaulted roofs of the minster founded by the Confessor must be regarded as more and more inadmissible; and that not for his own lack of merit, but from the physical conditions of the case. Room is limited, and each demand for space leaves a smaller space for the next demand. Room, indeed, is also limited for tablets or works of sculpture; but in this case the demand is usually more modest, and the available room is more ample. We look forward to the time when the walls of the cloister of Westminster Abbey shall be as attractive as those of the Campo Santo of Pisa; not from the treasured memorials of ancient art, but from the records they will offer of the names of the good, the great, and the lamented.

But let us keep to the instance now before us, because it is one as to which there will be no occasion for dispute as to the force of the claim. Tablet, statue, or memorial window to Carlyle we should gladly see erected in the Abbey. But that Great Britain would lose had his remains not been laid to rest in the country churchyard, there to be commemorated also by a suitable monument, we also feel. The two commemorations are not mutually exclusive; were it so, we should still hold that there was a truer pathos, if not a higher moral lesson, attaching to the local than to the public monument.

There is probably no uninspired writer who has so thoroughly grasped the idea that the history of a nation as of an age is the history of its greatest men, as did Carlyle. We used the adjective, not as either appreciative or depreciative of the Scottish writer, but simply as indicating, in passing, that this is a postulate underlying all our sacred writings. It is possible to reduce hero worship, like any form of idolatry, to the ridiculous, by sheer excess. But it would be difficult to attribute so much mischief to such an excess as is likely to spring from the reverse assumption from such popular teaching as that of the "History of the English People" and other works in which the force of public opinion, the influence of the masses, and the like are held up as the motive powers of history. We should perish with cold if we attempted to inhabit Mont Blanc. But as a feature in scenery, a poetic force and entity, what is the contrast between such a snow-clad peak and the "boggy syrtis" of the delta of the Nile? Thus for the training and elevation of the young, there is nothing like the history of great men. And their histories are at once made vocal and illustrated to the eye when we visit their cradles, their homes, their tombs. What is the difference of the effect produced by the statue of Shakespeare in the British Museum, compared with that of the bust at Stratford-on-Avon? The first is a fine work by a great sculptor; the second an ordinary bit of stone-cutting. Yet men go on a pilgrimage to see the latter, who are unaware of the existence of the former. It is at Stratford that we can best read our Shakspeare, and the hold of that great enchanter on the mind would, we venture to say, be somewhat less than it is if he were buried at Westminster. At all events, apart from the memory of the man, the charm and interest of a locality are enhanced by due memorials of its children. A monument which, in a country church, is an object of fascination, is reduced to very mean proportions in the companionship of a metropolitan Campo Santo. Whatever be the upshot of the contest between centralisers and decentralisers in matters political, let us remember that by the centralising objects of art we form not monuments, but museums. When

a man, or a painting, or a statue, is once ticketed and put upon the shelf, the next process is to forget him.

PRACTICAL RECLAMATION.

Recent discussions, to which this is not the place further to refer, as to the practicability or the reverse of reclamation on a large scale, have elicited some very valuable direct testimony from Mr. George Greig, who writes from Ochill Park, Bridge of Allan, as to reclamations begun in 1876 on Auchintoul Farm, Kinbrace, on the estate of the Duke of Sutherland.

For several years past works of reclamation have been in progress on his Grace's property, first at Lairg on Loch Shin, and subsequently at Kinbrace. The first were financially unsuccessful. The expenditure incurred in the Lairg works amounted to 100,000*l.*, in reclaiming 2,000 acres. This is at the rate of 50*l.* per acre, and the rental to be expected, viz., 1*l.* per acre, is manifestly inadequate to cover the outlay. But in this case,—as in so many others,—a large portion of the outlay has to be set down to the cost of education. Personal supervision of the requisite character was wanting, and there was a lack of experience in the use of steam cultivating apparatus. Since that time experience has done much to develope new and more effective implements, and consequently large saving has been effected.

Mr. Greig assumes the entire responsibility, as manager, of the reclamations commenced in 1876 on Auchintoul Farm, Kinbrace. The work has been in steady progress for more than four years, and when completed, next year, nearly 1,400 acres of land will have been reclaimed from the waste, and fully cultivated, at a total cost of 40,000*l.* This cost, moreover, includes not only trenching, draining, clearing, fencing, roads, houses, and lime, but also an outlay of 5*l.* per acre for fertilisers, work, and seeds in laying down the land as pasture. The price, little over 28*l.* per acre, or 23*l.* per acre for reclamation, *plus* 5*l.* per acre for getting in the first manured crop, contrasts very favourably with the expenditure at Lairg, of 50*l.* per acre. Nor are we left to mere paper calculations. In June, 1878, after 20,000*l.* had been expended on the work of reclamation at Kinbrace, the Duke of Sutherland had a formal offer made to him by one of the largest and most successful Scotch sheep farmers to take over the reclamations here made, to take over the extension of them to 3,000 acres, and, on these proving successful, to that of 2,000 acres more, paying a yearly rent for the same at the rate of 3 per cent. on the capital expended. A further proposal was to pay a rent of 7*s.* per sheep on the original capacity of the farm, and to back this offer to the amount of 3,000*l.* per annum rent.

Mr. Greig further points out that the greater part of the outlay on reclamation passes into the hands of the Duke of Sutherland's small tenants and crofters, and that a further sum goes to the Railway Company, of which his Grace is a principal shareholder. Since the passing of the Limited Liability Act, it is estimated that a sum of not less than 180,000,000*l.* has been speculatively invested in other countries and entirely lost. Here is a practical instance of the carrying out of our former recommendation as to lands that want hands. In 1880, out of 56,815,354 acres in Great Britain only 32,101,909 were under culture. Out of 20,819,947 acres in Ireland, 15,357,856 were under culture. Out of 25,938,286 persons living in England and Wales, 801,126, exclusive of vagrants, were in receipt of parochial relief. Here we have money that wants employment, hands that want employment, land that wants culture. Is it an insuperable problem to bring these mutually advantageous elements into relation?

The Growth of London in Streets and Houses.—The report of Lieutenant-Colonel Sir Edmund Henderson on the Metropolitan Police for the year 1880 has been presented to Parliament, and published as a Blue Book. In it Sir Edmund says that "no less than 24,945 new houses were built during the year, and the length of the new streets and squares opened and coming under the protection of the police was within a few yards of seventy miles. The number of new houses considerably exceeds those built in 1879, and is nearly three times as many as were built in 1871."

RAILWAY MOVEMENT OF 1880.

Although the "Railway Returns" for 1880 have not yet been issued by the Board of Trade, —a slackness of which the business world has great cause to complain,—we can set before our readers some of the main features of the movement, as ascertained from the "Statistical Abstract for the United Kingdom from 1866 to 1880," to which we have had occasion to refer for other information.

It may be most convenient to our readers if we place side by side the figures thus arrived at, and those of the "Railway Returns" for 1879.

Length of railways open in the United Kingdom:—

1879	17,696 miles.
1880	17,945 "

Total capital paid up in shares and loans:—

1879	£717,003,489
1880	723,621,657

Number of passengers conveyed (exclusive of season-ticket holders:—

1879	582,732,890
1880	603,834,752

Number of passengers per mile:—

1879	31,800
1880	33,652

Total traffic receipts:—

1879	£59,395,282
1880	61,958,754

Traffic receipts per mile:—

1879	£3,356
1880	3,454

Working expenses:—

1879	£32,045,273
1880	33,592,349

Net traffic receipts:—

1879	£29,731,430
1880	30,985,094

From the above official statements it may be calculated that the increase of the year is in the subjoined proportions:—

Length of line	1·4 per cent.
Capital	1·6 per cent.
Passengers	7·3 per cent.
" per mile	5·7 per cent.
Traffic receipts	4·3 per cent.
" per mile	2·8 per cent.
Working costs	4·5 per cent.
" per cent. of income,	from 52 to 54 per cent.
Net traffic	4·2 per cent.
Proportion of net receipts to paid up capital, from 4·15 to 4·25 per cent.	

FROM LONDON TO LONDON.

Fully 4,000 miles from its ancient namesake, situated in the midst of what is, perhaps, the finest agricultural region in all Canada, is the little city of London, in the county of Middlesex, and in the province of Ontario. It lies a little north of Lake Erie, and somewhat east of Lake Huron, and is built upon the banks of a small stream called the Thames, a river thereabouts just as large as the English Thames is at Hampton Court. London has a bustling population variously computed at from 27,000 to 30,000 souls. It is 120 miles from the Niagara Falls, which lie due east of it, and about the same distance west is Detroit, which is a large and beautiful city, just across the river, upon the United States side. London contains some good streets, and numerous public buildings. Some of the thoroughfares are called after the best known ones in old London, and Westminster and Blackfriars bridges lead one across the narrow silver line of water they have dubbed the Thames. There are two railway-stations, the principal one a good building built of white brick. It is not a terminus, but an open station with wide platform, and the name London stuck up in the middle, in large letters. There are good waiting, washing, and refreshment rooms. Just outside the station is an immense hotel, built, as the station is, of white brick. It is known by the no means euphonious name of "Tecumseh House."

London contains several excellent hotels, especially so is Grigg's House, which, like Tecumseh House, is an hostel hard by the station. There the passing visitor may live "in clover," for as long as or as short a time as he likes, for the moderate cost of one dollar and a half a day (6*s.* 3*d.*). This charge includes everything. In Canada no gratuities are ever expected by "boots" or chambermaid. London in its railways has important connexions. Northward, *viâ* the Grand Trunk, it goes to St. Mary's, southward to Port Stanley, on Lake Erie; westward, to Petrolia, the oil centre; and to Port Sarnia, at the entrance of the St. Clair River into Lake Huron.

The building trade is brisk just now in London, and, indeed, throughout all Canada. The summer sun,—over 100° in the shade, very, very often,—is exceedingly trying, especially as in winter, I believe, the cold is intense; but, notwithstanding, the climate is a healthy one, and although one does not see the stout, jolly-looking men often met with in England, yet everybody looks hard and "wiry." Bricklayers just now are paid $2 50c. a day of ten hours (10*s.* 5*d.*); stonemasons, $2 50c. to $3 (10*s.* 5*d.* to 12*s.* 6*d.*); plasterers, $1 75c. to $2 (7*s.* 3*d.* to 8*s.* 4*d.*); joiners, $1 75c. (7*s.*); hodmen and labourers, $1 50c. (6*s.* 1*d.*). There are several firms of architects in the city. The one who seems to have the most practice is that of Messrs. Tracy & Durand. Mr. Tracy is the city engineer. Messrs. Craddock & Weekes, Peters & Son, and W. Jones also seem to do nice businesses. There are a score or more of building firms in the place. One may remark, passing by, that a glance at the "Directory" shows how the predominant names in England, are, precisely as proportionably plentiful here. As mentioned above, the outside number of population the place contains is 30,000 folks, yet amongst them there are 160 householders rejoicing in the patronymic of Smith, whilst there are forty-six Mr. Joneses, and thirty-five Robinsons.

The principal job at present in hand is an exceedingly imposing block of buildings, known as the Masonic Hall. It stands at the corner of Richmond and King streets, and has also a plain back frontage toward the market-place. This building, which is in the freely-treated French-Classic style of architecture, is being erected from the designs of Messrs. Tracy & Durand. It is built of red brick, with stone dressings, and is of an ornate character. On the lower floor are shops, and over the first-floor windows will be a wide band of subject tiles. These are now being executed by Messrs. Minton in England. To the main entrance there are polished Scottish granite columns, and much well-carved detail is scattered over the two main façades of the edifice. The building is undoubtedly one of merit, but an eye fresh from England views with regret the sham galvanised iron,—what shall I call them? —dressings (!) that, upon close inspection, mar the good impressions made at a little distance. Galvanised iron takes a prominent part in the major portion of most colonial buildings. Upon this new Masonic Hall, for instance, all the top window fronts and the upper cornices, which at first sight look like solid masonry, consist of nothing in the world but galvanised iron, painted a light stone colour. Again, nearer the eye, just over the shops, is a cornice 2 ft. 6 in. deep, well moulded and elaborately carved. It runs round the building, and is apparently in brown stone; a glance, however, reveals the fact that all this detail is simply iron painted brown and sanded! The job is nearly complete, the contractors for the work being Messrs. Goldsmith & Parrett, bricklayers,—Mr. Goldsmith, who seems to have been much respected, died last March,—Mr. Mathieson, stonemason, Mr. Noble, painter, Mr. Mackintosh, plasterer, and Messrs Green & Co., carpenters. Near to this building, a little higher up Richmond-street, three large wholesale stores are building. They are from the designs of Messrs. Peters & Son, architects, and are in white brick, with light coloured Ohio stone dressings. Mr. W. H. Peters, originally a Devonshire man from Honiton, is the clerk of works; this job is about half up. Amongst other works in hand is a good mansion in the Dufferin-avenue; Messrs. Craddock & Weekes are the architects. The cost of this building, which is just having its roof put on, will be about 10,000 dols. A club-house, in Queen's-avenue, is also in hand at a similar cost under Messrs. Tracy & Durand. These gentlemen have also a fine Baptist chapel erecting in Talbot-street. It will cost 12,000 dols., and from their designs a mansion in red brick and Cleveland stone dressings is being built for Mr. Cronyn, barrister-at-law. The probable cost of this house is from 20,000 dols. to 25,000 dols. Some good shops have just been built at the corner of King and Market streets.

The badness of the roads in Canada is proverbial, whilst the "side-walks," as they call the pavement, are worse still. These side-walks are not of stone flags, but formed entirely of 3 in. deal planks, generally laid parallel with the

houses, but sometimes at right angles thereto. In some cities in Canada these wooden pavements are much worse than others. At Quebec, for instance, the culminating point is reached, and my great wonder is that, from constantly putting their feet through holes in rotten boards, half the folks there do not break their ankles. The badness of the Quebec paving is so far recognised, that the Canadians themselves have a saying, that "New side-walks are first fixed down at Toronto, when half-worn out they are taken to Montreal, and when entirely done for they are ready to transplant for use at Quebec!" A few of the streets, notably Richmond-street, which, crossing Dundas-street at right angles, forms with it the two main thoroughfares, have the side-walks macadamised. At present, under the direction of Mr. Tracy, the city engineer, or city surveyor, as we should say in England, wooden blocks are being laid down in Dundas-street; 12,000 ft. of it have been undertaken, the contractors being Messrs. Stevens, Turner, & Burns. A little street leading from Dundas-street to the Market-place, along which much traffic goes, was laid with blocks some time ago, and the treatment seems a great success; indeed, at Detroit and some other American towns, I believe, the blocks have long been in use. They are all 7 in. blocks, of course swamp cedar, laid endways of the grain upon river gravel and fine sand. The section the road-line is made to take is that of a wave mould,—a bold crown in the centre, with a sweeping gutter.

The Post-Office is a good building, and one of the best sites in the place is occupied by the Federal Bank of Canada, at the corner of Richmond and Dundas streets. They possess fine Gothic premises, built of brick and Cleveland stone. There are many fairly good churches and chapels, and upon the outside of the city are not a few handsome villas. The roads are laid out at right angles to each other, and are wide and commanding. The streets in the main part of the town are innocent of trees, but immediately the suburbs are gained long rows of lofty trees line either side, and with the thermometer at 102° in the shade, as it is at the moment these lines are written, offer a grateful shelter from the burning rays to the pedestrian. At night the city is well lighted by gas. The gas company have, I understand, great facilities for the manufacture of this commodity, so much so, that London is at present supplied with gas at about half the price of any other city in the Dominion. Along the main streets, double rows of telegraph-poles run. These are of huge proportions, 18 in. and more through at their base, and running 40 ft. or 50 ft. high. Upon the poles down Dundas-street thirty-four lines of wire run. Tram-cars are in great request, and seem to roll along everywhere. The uniform scale of charge, as elsewhere in the Dominion, is 5 cents. (2½d.). London possesses a fine public park, with a handsome band-stand in its centre.

Taking it altogether, the place is a thriving and prosperous city. The sad accident to the *Victoria*, some two months ago, when nearly 200 souls perished, filled every one with gloom, but that has passed now. I walked a mile down the river's banks, and meandered amongst the big trees at the spot where the catastrophe happened, and could scarcely realise how, in such a wee stream, not one whit, as mentioned before, larger than the Thames at Hampton Court, so many lives could have been lost. The Canadians are pre-eminently loyal, and London is in no way behind in this respect. A review took place the other day, at which I was present, wherein 2,000 volunteers took part, and very fine fellows many of them were.

The most interesting place in all London, perhaps, to the thoughtful and kindly-hearted Englishman is the Guthrie Home at Westminster. Westminster is a suburb two miles or less from the heart of the city, and there at the present moment are some 500 or 600 orphan children, all of them waifs and strays from Britain's capital, from Birmingham, and other large English towns. The children are brought over in batches of 100 or so, boys and girls, from three up to twelve years of age; they are well cared for, and are ultimately adopted out into comfortable families in this country, where they generally find happy homes.

Bound upon a holiday scamper through America, I crossed the Atlantic, a couple of months ago, in the steamship *Parisian*. Therein were between sixty and seventy of these dear children, under the care of Miss Blackhall, a lady who has already bravely and without a murmur faced the horrors of a steerage passage across the angry ocean more than a dozen times on similar missions of mercy. I can testify that during the nine days occupied by our voyage, no children could have been better behaved, none more loving, none more kindly and helpful to each other, than were these waifs, not long ago the scum of the streets, but now, thank God, warmly dressed, well fed, and happy juveniles. During the first few days, the weather being rather rough, they suffered considerably, and it was pitiably curious, if one may use the expression, to see them brought from below, and laid helpless, just in piles, one over another, upon the lee and sunny side of the ship. Very white-faced and dead-looking they were then; but a transformation soon took place: the sickliest child pulled up wonderfully, and ere we had accomplished one-third of our voyage, they were skipping (every little one was provided with a skipping-rope) everywhere, and singing Sankey and Moody's hymns. In fact, the happy laugh of these poor lambs was the sweetest music in all the ship, and fairly infected every one of the thousand souls who found within her a home for the time being. May God prosper the work in hand, and may many thousands of our poor city Arabs find a home in the new land that is ready and able to receive them.

I am not altogether prepared to say whether I can honestly recommend our working men generally to leave old England and come hither. At present I see the country under its best face. It is the month of July. Everything is bright and sunny, and the demand for all sorts of labour is greater than the supply. But I am reminded that the winters are long and severe; that for six months in the year employers too frequently "shut down," or, as we should say, "stop" all the out-door jobs, and then the men have to do the best they can. This set-off in the shape of intensely cold winters is a serious consideration,—especially for those engaged in out-door trades.

London lies upon a flat site; its men are sober, its young women very pretty, and everybody seems fairly prosperous. I have not seen in it a really poor person; nor a single house where squalor and abject poverty look out from the door. Possessing a fair acquaintance more or less with most towns in England, on reviewing them in my mind's eye, Southport, the new Lancashire watering-place, reminds me more than any other place in our own country of the well-to-do city I am now visiting.

My space is filled. From "London in the Bush" to "London in the Smoke" (that is how the good folks hereabouts define the two cities), I waft a kindly greeting! HARRY HEMS.

THE FRANKFURT PATENT AND TRADE-MARK EXHIBITION.

THE days are long gone by when Dannecker's much-admired Ariadne in the Bethmann Museum formed the principal attraction in Frankfurt for all travellers on the Continent. The sons and daughters of Albion especially made it a point to see that masterpiece of the eminent sculptor. At the present day there is something else to be seen and admired. Round the nucleus of the old imperial free-town of many-pointed gables have clustered quarters of palace-like mansions and suburbs of charming villas. At the western end we are invited by the Palmengarten and the rotunda of the Diorama (battle of Sedan), and in the east by the Zoological Gardens. The new Exchange rises behind the old theatre; the new Opera House, by Lucä, at the Bockenheim Gate; the Städel Institute (the picture gallery), on the other side of the Main, in Sachsenhausen. Next to the completed Cathedral, described on a former occasion in these columns, in one of the oldest parts of Frankfurt, we behold the new Städtische Archiv, erected in the Gothic style by the architect Denziger, with its imperial manuscripts and documents from the time of the Carlovingians, and the rich collections having reference to the past history of Frankfurt, all securely housed in the ground-floor.

To all those permanent sights and curiosities of the city, another has this year been added. We are referring to the Patent and Trade-mark Exhibition opened on the 1st of May, and now in the midst of its success. The attractions which it offers have caused thousands of visitors to Frankfurt this summer, numerous at all seasons, to direct their steps to the exhibition. "Steps" is only a figurative expression, for tram-cars and other vehicles shorten the distance very much, the buildings and gardens constituting the exhibition being outside the city. On the opening day it suffered from the chronic disease of all exhibitions, unreadiness; but, of course, it presents a very different picture now, and leaves nothing to be desired on the score of sight-seeing. Two arrangements in the gardens especially act as powerful magnets, and both are of Berlin descent: the excellent and well-known band of Bilse, and Siemens and Halske's electrical railway. The latter is never at a standstill; from the hour of opening to the time of closing most of the carriages are filled, and even the beholder looks upon it with interest, silently conjecturing what an important *rôle* this mysterious motor may yet be destined to play in the history of civilisation. Actuated by the same power, the electrical lift carries the curious to the top of the high tower, from the upper platform of which a splendid view is obtained of the city, the plains surrounding it, and the far and near hills enclosing the horizon. Another point of attraction is the large telescope, only recently completed. As far as we know, this is the first opportunity offered to the general public of observing the stars. It is unfortunate that this enjoyment cannot be so easily obtained as the others that may be had at the exhibition, for entrance to it is restricted to but few hours. The eagerness of the public for admittance is very great, and each one has to wait his turn. The visitor is here enabled, under the guidance of Dr. Harzer, the astronomer of Leipzig Observatory, to observe, from four to six in the afternoon, sun spots and protuberances, and, after the setting in of dark, lunar landscapes and stars *ad libitum*, or aspire to the discovery of new comets. It is reported that this valuable instrument, constructed by Dr. Schröder, of Obersursel, near Frankfurt, will probably be acquired for the city.

An exhibition of an exceptionally valuable nature is the historical exhibition of the Frankfurt Artists' Society, only lately opened. A small but charming Ionic temple rises between the grand entrance to the exhibition and the balneological exhibition, the columns and pediments of which have been chromatically decorated, conveying a pleasant impression to the beholder. One is astonished to find in this little building three large rooms, the walls and other spaces of which are covered with a number of oil and water-colour paintings, drawings, sketches, copper-plates, studies, and casts of sculpture, all works of Frankfurt artists, or such as have resided for a longer or shorter time in the city, amongst whom appear also Hans Holbein the Elder and Peter Cornelius. This exhibition of Frankfurt art thus comprises a series of brilliant names, such as Hans Sebald Beham, the Frankfurt artists' families of Merian and Roos, Theodor de Bry, Schütz, &c., down to the great masters of our time, Cornelius, Overbeck, Veith, Steinle, Schwind, and their disciples and successors, such as Leopold Bode and others. Of especial interest are two landscape drawings of Goethe's, lent by the Weimar Museum.

The chief ornament of the exhibition grounds is formed by what the Germans call "carpet-gardening," and for which Frankfurt is well known,—a style of gardening to which we in England, and London especially, have been long accustomed in our parks. An establishment devoted to enjoyment has only just been thrown open. It is a skating-rink of real ice. The great drought and consequent scarcity of water has been the cause of the delay. This ice saloon will probably be more an object of curiosity than of actual use, for only the most enthusiastic skater would voluntarily undergo the exertion involved in the hot season.

We have described the most salient points of attraction for the ordinary visitor to the Frankfurt Exhibition. It is now time to direct attention to its features of a more practical nature and of greater utility. If we look into the great boiler-house, we find there three boiler systems in operation. Messrs. Walther & Co., of Kalk, introduce Root's tubular boiler with patent tube joints and an ingenious steam-collecting apparatus. The second boiler used in driving the machinery of the exhibition, a MacNicol circulating boiler, is shown by Messrs. Hetzler, Kolb, & Karcher, of Beckingen on the Saar. The third boiler, also tubular, is by E. Willmann, of Dortmund. A criticism of the various systems is not possible until the results of the projected scientific and technical examinations are to hand;

but it may be generally remarked that in all three the makers have endeavoured to obtain a large heating surface on a small section by means of the tubular system, and thus to secure a free circulation of the water in the boiler, while no novelties have been introduced in the system of firing. A tubular boiler by Joseph Prégardien, of Deutz, which is not in operation, attracted last year at Düsseldorf favourable and well-deserved attention. In this division, the boiler for central low-pressure steam-heating exhibited by Ad. Bechem, of Hagen, also deserves notice, being suitable especially for warming private houses cheaply and uniformly.

Of particular technical interest are some boiler fittings, partly shown in operation; for instance, the automatic feed-apparatus of S. G. Cohnfeld, of Zankeroda, and the feed-water heaters and injectors of Gebr. Körting, of Hanover. The exhibits of the latter firm in the patent section should not be overlooked, being interesting even to uninformed persons, demonstrating, as they do, in how many ways the well-known simple principle of the Körting injector has been applied to industrial and sanitary purposes. Besides the various injectors, the automatic railway brake of Sanders, of which a working model is shown in connexion with a Körting injector and suction apparatus, ought to be mentioned. The principle of this vacuum brake, which has been introduced on several German and English railways, and which has proved efficient especially in checking trains on gradients or in curves, is now pretty generally understood, but we may just mention for the benefit of those of our readers who are not thoroughly acquainted with its working that it consists in fixing on each carriage of the train brake cylinders the hollow spaces of which are kept in a state of vacuity, in consequence of which the brake-blocks are held away from the wheels. As soon as, by the opening of a stop-cock, the state of vacuity in the cylinders is either wholly or partially reduced, the brake-blocks are pressed with corresponding force against the wheels. By means of pipes along the whole length of the train, all the brake cylinders are momentarily brought to the same state, the engine-driver being enabled to regulate their vacuity, consequently also the force of the brake, by the aid of a vacuum meter fixed on the engine. In case of a rupture of a train the brake must, as a matter of course, act automatically; but, generally, no carriage can be checked independent of the action of the driver. The same firm show in the balneological section of the exhibition other very interesting applications of the principle of the injector.

If we take a further look into the patent section, the display made by another good firm, Messrs. Klein, Schanzlin, & Becker, of Frankenthal, awakens lively interest. We notice, in the first place, several steam-pumps, working very smoothly, of but modest dimensions, but of very great power, which raise the water for the exhibition. The same makers have also supplied for use during the exhibition an independent boiler feed-pump, with suction and delivery air-vessel in frame, in which the boiler-pressure amounts to ten atmospheres, and a coupled plunger-pump, with post serving as air-chamber, used as water-pump for the ice-machine. The two pumps exhibited at Frankfurt are provided with Klein's adjustable crank, very efficient in preserving a uniform motion. The capability of the two pumps will best be illustrated by stating that they raise 15,405 imperial gallons of water per hour to the height of the reservoir in the water-tower, 115 ft. from the ground. This water supplies the fountains, &c., and runs after use into a collecting basin, whence it is raised again and again to the water-tower by the Klein pumps. If the clackpiece is left out in these pumps, they still constitute a steam-engine useful for performing small work. These pumps also show the patent suction and delivery valve, of importance on account of the regular and steady action, and which has proved efficient in pumps both with slow and quick motion. The Klein self-tightening stopcocks, which do not leak, and are of greater durability than ordinary cocks, also deserve attention. Made of iron, they are very extensively used in chemical factories. The same Frankenthal firm likewise exhibits in action the Lux oil testing apparatus. This instrument is used for comparing different descriptions of oil with regard to their lubricating properties, a curved line drawn upon a paper cylinder giving an exact view of the lubricating property of oil for several hours. For railways and industrial establishments using much oil this testing apparatus is of no small value, especially as it shows at the same time which alloy is best suited for axle-bearings.

The Körner apparatus for consuming fire-damp by chemical means (shown by L. Frobeen, of Berlin) is a most ingenious arrangement. This apparatus consists principally of a Ligroin lamp, the chimneys of which are provided with asbestos caps. The asbestos is impregnated with platinum and palladium, so that the fire-damp is consumed without danger at the red-hot caps. This lamp is, at any rate, a most remarkable endeavour to render fire-damp, which plays such havoc in our coal-mines, innocuous in a chemical way, instead of, as hitherto, by physical means. The same firm exhibits two rock-drilling machines, in which air is compressed in a cylinder by turning the crank, which throws the drilling-bar forward, and at the same time revolves and pushes it on ahead. Another object worth notice is a feed-apparatus for air-chambers, and an ore stamp-mill. A very important and powerful apparatus for ventilating rooms is the turbine ventilator, with hydraulic power, which may also be made in the form of a stove with either pulsating or aspirating action.

We have thus brought our notice of the Patent and Trade-mark Exhibition now being held at Frankfurt to a conclusion, and drawn the attention of probable visitors from England to such sights and exhibits as ought not be overlooked by them. We have shown that the exhibition is in some respects a remarkable one, as is further evidenced by the fact that such an important body as the Society of German Engineers, which will hold its annual meeting (the twenty-fifth year of its existence having elapsed on May 12th last) at Stuttgart, from August 22nd to 25th, have thought it worth while to pay a preliminary visit this week to the exhibition before assembling at their trysting-place. The exhibition is a proof of the benefits conferred on the nation by the German Patent Law, which has been in operation only a few years. Another point of really practical importance, not to be overlooked, is that inventors will be enabled, through the opportunities given by the Exhibition Committee, to derive pecuniary profit from their inventions, that body having undertaken to be the disinterested medium between the inventive genius and the capitalist.

THE OLD JESUIT CHURCH AT MÜNSTER, WESTPHALIA.

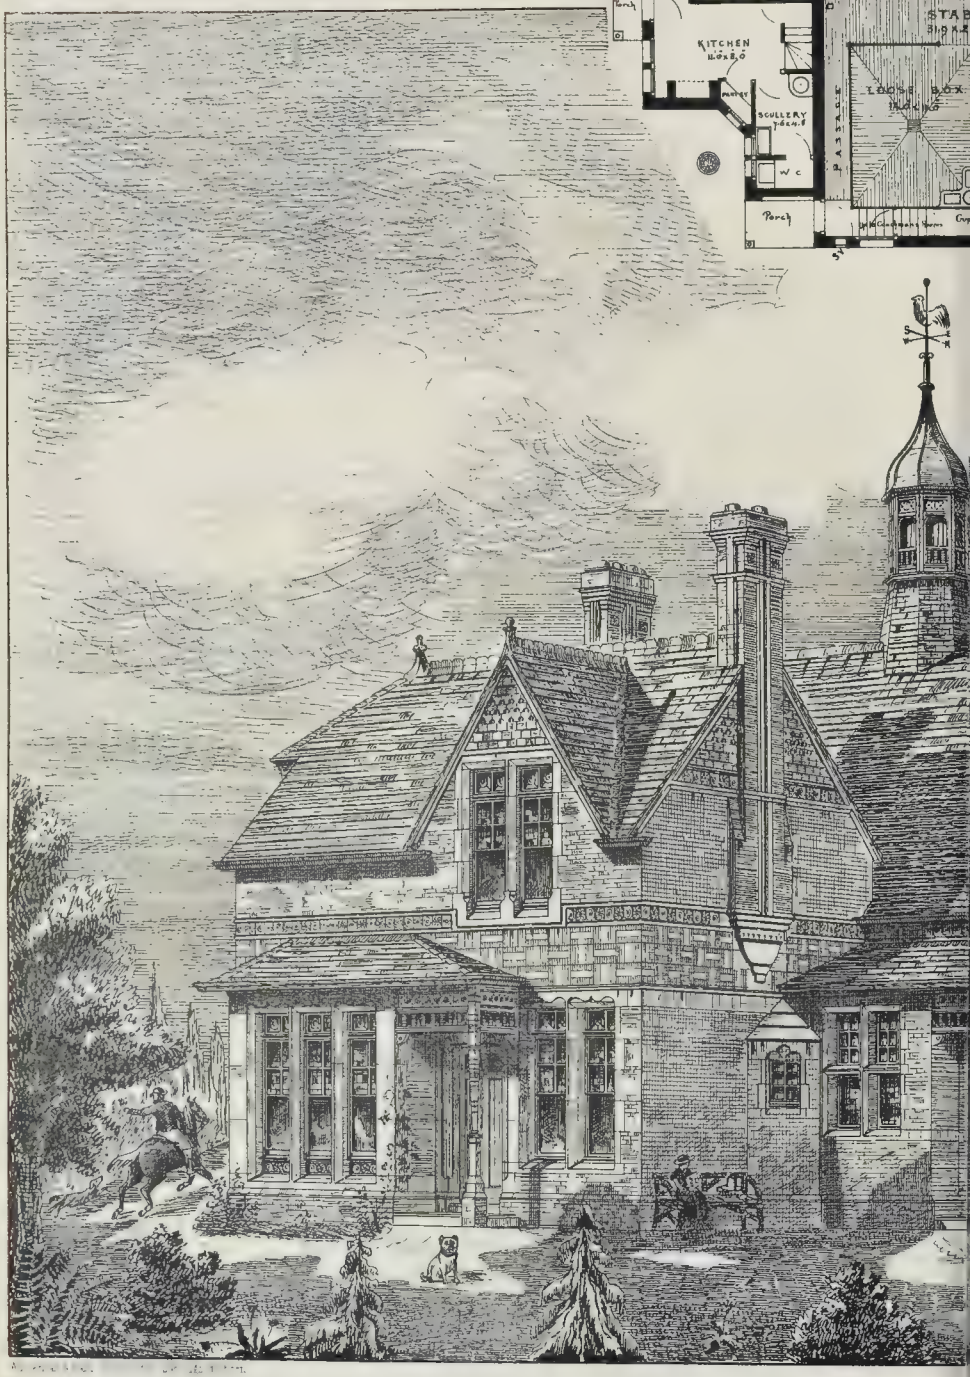
The building of which we give an illustration at present serves as a chapel to the great Public School or Gymnasium at Münster. It was, however, formerly the Church of the Jesuits, and served both as a place of worship for the students attached to the great college of the order, and for externs who desired to attend the services and sermons held by the fathers within its walls.

The first stone of this interesting church was laid on the 3rd of June in the year 1590, and the building was completed nine years later.

It consists of a long nave and aisles terminating to the east in a single apse. The aisles are two stories in height, both vaulted, as is also the nave. The upper story or division of the aisles forms a large kind of triforium or gallery. This treatment is common to the churches of the Jesuit order, and is to be seen in their churches at Cologne, Aix-la-Chapelle, Dusseldorf, Coblentz, Würzburg, &c. The students of the colleges which were attached to these churches used the galleries, and the general public were accommodated with seats upon the ground floor.

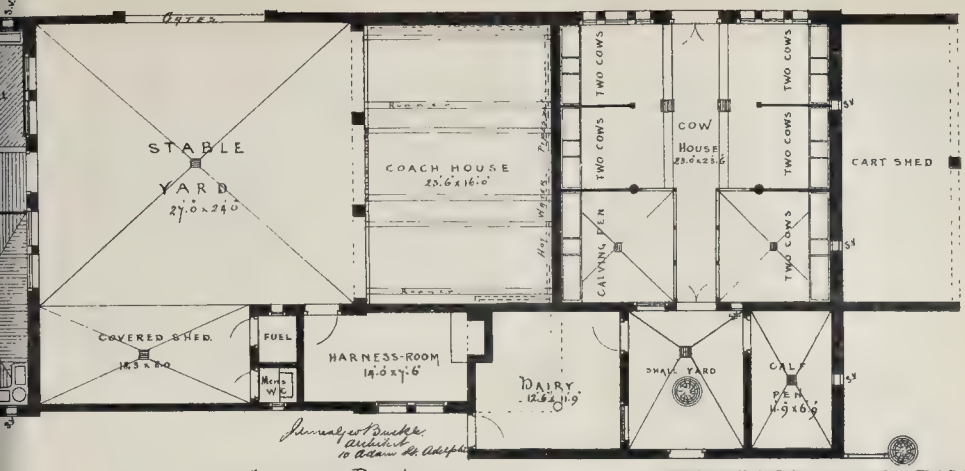
As will be seen from the view which we publish, the architecture is a curious mixture of Third Pointed Gothic, with the revived Classic of the period. The general plan and arrangement belong entirely to the former style, as do also the vaulting, window tracery, buttresses, &c., whereas the doorways and cornices partake of the latter. There is, however, a much more distinct Gothic feeling about the building than its date would have led us to expect, and, singularly enough, this is the case with most of the earlier churches erected in Germany by the same order. Of course, one would naturally have expected to have found exactly the reverse the case; yet, strange to say, the Jesuits were very nearly reviving Gothic architecture in Germany. Their churches at Coblentz, Cologne, and Paderborn, all erected after the commencement of the seventeenth century, are, especially internally, thoroughly Gothic in character, and it is, perhaps, not too much to say that the Jesuit church at Cologne is the noblest Gothic church erected anywhere since the year 1600. Its precise date is 1621—1629, and whether we regard it as the last great expiring effort of Gothic architecture, or as a most remarkable effort at its revival, it is a building deserving of very careful study.

One point to which we wish to call attention is the construction of the vaultings of these Jesuit churches. They are probably the latest examples of Gothic vaults, and their builders had profited by the experiments and experience of four centuries, and the result of this is the fact that these vaults appear to have no thrust. The walls of the clearstories of all the churches we have named are very thin and entirely without buttresses, though in the case of the church at Cologne the span of the vault is about 40 ft.! These vaults are composed of a rather acutely-pointed barrel-vault running from east to west, with lunettes cutting into it from north to south; the whole is covered with a rich network of ribs dividing it into triangular compartments. The spaces thus enclosed are exceedingly concave, so that each triangular space forms a kind of dome, and if a section be taken through the vault, except at the surface of the ribs, it will give the outline of a deeply-cusped arch, though the ribs all project to the face of what would in section be an acutely-pointed arch. At first we supposed that the vault was very much loaded, but a little examination proved this not to be the case, because these convex sinkings are continued right down almost to the cap of the vaulting shaft,—in fact, to the point where the ribs unite. The effect of this kind of vaulting is exceedingly ornamental, and its constructive excellence is shown by the fact that, although it rests upon remarkably thin walls they are not affected (those of the church at Münster do not appear to be more than 2 ft. in thickness), and we could discover no crack, opening, or settlement. We should mention that the ribs are stone and the soffit of the vault is constructed of small red bricks covered with plaster. The vaulting-ribs are very deep and narrow, and their section is more like that of a window-mullion than what we are accustomed to see applied to a vaulting-rib; the bosses are large and adorned with shields.



The fittings of the church at Münster, like those of all the other Gothic Jesuit churches we have seen, are quite Renaissance in character. The reredoses are well designed and piled up story over story in a very picturesque manner. Great attention appears to have been bestowed upon the doorways, which are remarkably pretty examples of "freely treated" Classic. The collegiate buildings attached to this church are in style very like our English Jacobean, and although slightly earlier in date than the church retain far less Gothic treatment than does the church itself.

PARIS.



It is proposed to establish a retail provision market in the Temple quarter to replace the ancient market of St. Martin, which will be shortly suppressed. There is also a question as to the establishment of a new market in the Plaine Monceaux, where the number of recent buildings erected makes the provision of a new market a matter of urgency. The open-air market in the Avenue Wagram is found to be insufficient, especially for the wealthy classes who have lately come into this neighbourhood, and who are obliged to seek their provisions in the centre of Paris. Two sites have been suggested,—one at the angle of Rue Ampère and Rue Brémontier, the other at the angle of Rue Ampère and the Avenue Wagram.

The municipality, not having been able to agree with the owners of the property, will be compelled to obtain the site by compulsory purchase, which will delay for some time the carrying out of the work.

Literary Congress, Netherlands. — A literary Netherlands Congress is to be held at Breda on the 31st of August, continuing till the 3rd of September proximo. It will be composed of Dutch and Belgians. It is divided into three sections, viz.:—1. Netherland language and literature; 2. History and archæology; 3. Theatre, music, plastic arts, and library. A committee has been appointed for the management of this business.

THE OLD JESUIT CHURCH AT MÜNSTER, WESTPHALIA: *Commenced*, 1590; *Completed*, 1599.

THE ENGINEER STUDENTS' QUARTERS, KEYHAM, DEVONPORT.

The site of the new College for Engineer Students at Keyham-yard abuts on the Saltash-road, overlooking Keyham-yard in its rear, and the Hamoaze, with its naval anchorage, to the north. The new quarters occupy an area just beyond the official residences, and the buildings are on the same level, some 30 ft. above the floor of the yard. The plans were prepared at the Admiralty Office, Spring-gardens, under the direction of Colonel Pasley, C.B. The main building, which is of three stories above the basement, has a frontage of about 200 ft. This, the principal elevation, has in the centre a tower, carried up from the entrance, slightly in advance of the flanks, and higher by one story than these, or the wings, somewhat similar in design, which complete the frontage. The materials used,—limestone ashlar, with Portland dressings,—are well adapted to the style. Mullioned and transomed windows fill in the openings. The upper story has dormer windows; the tower and wings, having Mansard roofs, are finished by a bold cresting of Macfarlane's ornamental ironwork, with gilded vanes.

The site is rectangular, and slopes to the north and rear, the basement occupying the declivity, and bringing the ground-floor to a level with the high-road. The design of the main building takes the form of the letter I reversed, and the premises, with the narrow courtlage surrounding them, occupy all the space at the architect's disposal. There are three exits opening on the courtyard, in addition to a "tradesmen's porch," and the entrances to the cellars and stores. Roughly speaking, the premises consist of the officers' and students' residential quarters, which, with the spacious study and recreation hall, occupy the frontage, the mess and lecture hall in the centre of block, immediately beyond the main entrance, and the kitchens and servants' quarters flanking them in the rear. The basement of the frontage underlies the tower and the north wing, the former occupied by the coal-cellars, the furnace-room of the heating system, and a fine suite of baths and lavatories. The rear-block basement, under the kitchen and servants' quarters, is given up to the cook and steward, and contains, besides two rooms for each of these functionaries, a long range of cool and dark larders, the coal-cellar, knife and boots room, and other offices. In the yards are the latrines, separate, well-fitted, well-ventilated buildings, each capped by a flushing-tank of some 3,000 gallons capacity. The servants' latrines are fitted up on the system of Macfarlane & Co., who have given much attention, and with considerable success, to the arrangement and appearance of structures of this kind.

We give a view of the principal front, and plans, which will sufficiently show the accommodation provided.

Above the basement one side of the building is a *facsimile* of the other, the entrance-hall and tower rooms standing between. The former, the vestibule, is reached by a short flight of steps, steps again lead to some small rooms under the tower, and more steps to the great hall. The misfortune of the building in respect of site is apparent enough in the necessity for these gradients, which dwarf the entrance and hall. From the entrance, which is flanked by messengers' lobbies, broad steps open to the vestibule, a stone-paved hall from which on either side a corridor branches. Upon the corridors neat suites of rooms, designated as officers' apartments, are placed, and the passages end at the common rooms of the college,—at one end the recreation-room, and at the other the study. The two rooms correspond exactly. Each of them occupies an entire floor of the wing, and has an area of about 1,500 ft., the dimensions being:—Length, 57 ft. 6 in.; width, 26 ft.; and height 13 ft. 9 in. They are warmed by Manchester grates, the speciality of which is a chamber at the back from which a current of heated air is continually being diffused. The windows of the recreation-room overlook the shipping in the Hamoaze; the view from the study windows is limited more closely. The only room in the building which is superior to these is the mess and lecture hall, where the advantage of superior height is seen. It occupies the central position on the site. Lighted from each side by five mullioned and transomed windows as well as by dormers in the lofty circular roof and a three-centred segmental window at the extreme end, it is luminous and airy. The roof is borne upon moulded timber ribs, springing from carved corbels. The only additional ornament is a pedimental entablature with voluted trusses, above the main entrance, which will support a clock. Hot-water pipes running the length of the hall provide for heating, and for ventilation there are several perforated discs in the roof, all communicating with a "trunk" above, which extends the length of the hall, and is fitted with one of Howorth's Archimedean ventilators, of large size. The ventilator is inclosed in a flèche. For evening use gas pendants hung from the roof are provided, and these centre in the ventilating discs already mentioned. The kitchen offices in rear of the mess-hall are provided with a special corridor, so that access may be had thence to the main building without entering the hall.

Each corridor has a flight of stairs leading to the upper floors. These are the dormitories for the students. Each flank is partitioned off into sixty-six little compartments, 10 ft. by 5 ft. 6 in. in area, with the regulation fixtures, bed, washstand, chest of drawers, and book-case. On each floor are two double-sized cubicles for superintendents. Down each gangway hot-water pipes run beneath the usual grating. Every cubicle is separately lighted, and is in all respects distinct. Sleeping accommodation is thus provided on each floor for sixty-six students and four superintendents, and the two stories devoted to the dormitories afford room for 132 students and eight superintendents, the space occupied being that of 148 cubicles. This arrangement leaves the tower-rooms untouched, and they are fitted up as officers' quarters. The height of the first floor is 11 ft. 9 in., and that of the second floor 13 ft. 9 in. Each wing has its separate staircase and separate offices of all kinds, as well as its own exit into the courtyard. Above the level of the dormitories there are two additional stories in the tower, which form the sick-bay of the establishment, with an attendant's room above.

The kitchen, a lofty room, 24 ft. square, and the scullery adjoining it, having been fitted up by Messrs. Benham & Sons, of Wigmore-street, London, with cooking apparatus sufficient for the daily requirements of from 150 to 200 persons. The ranges, which are fixed back to back, cover an area of 81 square feet. Large ovens for baking and roasting, and jacketed boilers for steam cooking, as well as appliances for steaming potatoes, heating water and plates, and supplying hot water to the baths, are found connected with the kitchen. A cylindrical boiler is fitted in the basement for the maintenance of this service, and a lift connects the kitchen with the stores. In the other wing of the rear block is a spacious servants' hall, and in the floor above are the servants' bedrooms. Dependent on the kitchen for hot-water supply, but otherwise detached from it, are the baths and lavatories, in the basement of the mess-hall. The space available for lavatories is divided into a sufficient number of separate enclosures for the whole of the students, and to each water is laid on, and a galvanised tub and sink fixed. There are five baths, supplied with hot and cold water. The floor, which is of asphalt, was specially laid by Claridge's Asphalt Company, of London.

The cost, as appears from the Naval Estimates, has been above 30,000*l*. The staircases are of teak; the passages below stairs are laid with York paving. The limestone facing of the walls is of stone from the Pomphlett quarries, and this is backed with a lining of brick. The Portland stone used in the dressings was prepared on the works by stone-dressing machinery. The premises are laid throughout with a hot-water system. The lift, which works from the basement to the upper floors, is fitted with Waygood & Co.'s automatic check. For the windows, the sash-fastener invented by Mr. Brenton, of Polbathic, is employed throughout the college. The buildings were erected by Mr. John Pethick, of Plymouth, under the superintendence of Mr. Tinkler, the Government clerk of works.

THE LATE MR. HARVEY EGINTON, ARCHITECT.

A well-known Shakspearian scholar is anxious to ascertain who has the papers of the late Mr. Harvey Eginton, the architect who restored Stratford-on-Avon Church in 1837. As this is to aid in a somewhat important Shakspearian inquiry, we willingly ask the question, and shall be glad to have it answered.

LODGE AND STABLE BUILDINGS, EDGWARE.

Our illustration represents stable buildings recently completed at Orange-hill, Edgware, for Mr. William Ruddock. The accommodation provided consists of five rooms in lodge; four-stall stable and two loose boxes, with loft and three rooms over the stable for coachman; coach-house for three carriages; harness-room; cow-house for twelve cows; calf-house; and dairy. Spacious lofts are provided in the roofs. The materials are stock-bricks internally with red facings. The window-sills and door-jambs are formed with white bull-nose bricks; Pether's bricks for the arches, and Brown's ornamental pateræ for the string-courses. The stable fittings and hot-water apparatus were supplied by Messrs. Marshall & Hatch. It may interest our professional readers to know that the stone dressings were executed with Beer stone, which, although exposed to the severest trials during last winter, failed only in one or two instances. The buildings were erected by W. J. Beale, of Battersea, under the superintendence of the architect, Mr. James George Buckle, of 10, Adam-street, Adelphi. The mansion to which these stables are attached is now being built by the proprietor without a contractor from designs and under the supervision of the same architect.

THE CLOISTERS OF THE "CONVENTO DE CHRISTO," THOMAR, PORTUGAL.

Among the architectural monuments of Portugal to which importance attaches, not only on account of their historical associations but their value also to the architect and archæologist with regard to their styles, must be placed the "Convento de Christo" of Thomar, one of the finest edifices in Portugal. Its early traditions are mixed up with those of the historic fortress of Gualdim Paes, Master of the Order of the Knights Templars, who established themselves in Portugal in 1125. The façade of this edifice was erected much later, namely, in the reign of Dom João III., the fifteenth king of Portugal, who reigned between the years 1521 and 1557. The building was considerably enlarged by his grandson, Dom Sebastião, who succeeded him on the throne; and, subsequently, by the three kings, Dons Filippe II., III., and IV., of Castella, who reigned in Portugal between the years 1580 and 1640. The edifice has attached to it more cloisters than any other convent in Portugal. These cloisters present to the discerning eye of the architect and archæologist specimens of a variety of styles extending through the various architectural epochs of that kingdom, and including the Renaissance from its first introduction in the ecclesiastical architecture of Christendom down to its most flourishing epoch.

We intend noticing here briefly only the cloisters, one of which we illustrate. This adjoins the chapel, and is of small dimensions; it is devoid of any considerable amount of ornamentation, but is of solid construction. It bears unmistakable marks of antiquity, and is said to be co-eval with the first foundation of the Knights Templars in Portugal.

Two other cloisters were erected by the Infante Dom Henrique, one of which is at present in ruins, and which was partly destroyed during the fatal period of Vandalism during which all the monuments of Portugal suffered. Another cloister, called "Santa Barbara," was erected by King Dom Manuel; it is small, but of handsome appearance, and in the Gothic style. Another larger cloister, adjoining, is mediocre in execution, and without attraction and beauty. The same may be said of that called "Corvos." The cloister called "Mixo" is only remarkable as permitting a view, through one of the openings of its upper walls, of the gates in the façade of the hall where, according to tradition, the three estates of the realm, the clergy, nobility, and commons, assembled at the call of King Filippe II. of Castella, in 1581. The cloister called "the Filippes" surpasses all the others in grandeur and excellence of execution. The superabundance of its ornamentation, and the multiplicity of its columns, far from detracting from its merits, combine to make it a most beautiful production of the Renaissance of that period in Portugal.

The cloister which we illustrate is that of the Cemetery used as the last resting-place for the members of the Order of Christ. It ranks early, as we have said, in the chronological order of the erection of the cloisters, and is a very late-

resting work. It displays pointed arches, supported by slender double columns, ending in elegantly-carved capitals in the Gothico-Byzantine style. The name of its architect is not known.

DISCUSSION ON SANITARY PLUMBING.

On Monday evening last there took place, in the Hall of the Society of Arts, Adelphi, a discussion on the lectures* delivered there during the last three months by Mr. S. Stevens Hellyer, under the auspices of the National Health Society, on "The Science and Art of Sanitary Plumbing." There was a good attendance, the audience comprising not only working plumbers, but many master plumbers, and several architects and sanitary engineers.

Mr. Ernest Hart presided, and in opening the proceedings read the conditions which have been laid down by the National Health Society for the working plumbers' competition for the prizes offered by the society for the best specimens of workmanship in plumbing based on sanitary principles. Any one who desires to compete must fill up a form to be obtained from the National Health Society, 44, Berners-street, and all such forms must be returned by the 15th of September.

Mr. Daniel Emptage, of Margate, led off the discussion by reading a short paper, in which he expressed his opinion that Mr. Hellyer's able lectures were calculated to do a vast amount of good in awakening interest upon the important subject of which they treated. He agreed in the main with Mr. Hellyer's remarks as to country shops, and with the advice given to young working plumbers to come up to London to improve themselves in their trade. At the same time, as a provincial man, he felt bound to say a few words on behalf of the plumbers of provincial towns, in many of which a very lively interest was taken in sanitary matters. In his own town there were many large scholastic and other establishments in which the sanitary arrangements were such as would be hardly found fault with even by Mr. Hellyer. As the result of a large number of practical experiments made during the last two years, he (the speaker) had arrived at the following conclusions with regard to trap-waving or syphonage, viz.:—1. That the ᔓ or P syphons are, when unventilated, very unsafe, from the fact that they are easily untrapped by waving-out or syphonage. 2. That the cast D, the "Eclipse," and the V traps hold their seals much more tenaciously than the syphons, but are still very liable under some conditions to become unsealed when not properly protected by ventilation. 3. That the old D is very much more difficult to untrap than any of the preceding traps, but even this, when without ventilation, is not safe from syphonage. 4. That the seal of a P syphon, even under the most favourable circumstances with respect to ventilation, is not safe against a rush of water passing rapidly through it. 5. That a well-made ᔓ trap, when properly ventilated, and fixed in connexion with a fully-ventilated soil-pipe, is very difficult to unseal. 6. That the other four traps mentioned are, when properly ventilated, quite secure from either waving out or syphonage, and they have the advantage of being so constructed that their connexion with the soil-pipe could be made at a much higher level than was possible with the ᔓ. They all have, however the great disadvantage of being more foul. Mr. Emptage went on to say that, while thinking over the matter, it occurred to him that the ᔓ trap might be so altered that, while retaining its non-syphoning qualities, it should at the same time allow of a connexion with the soil-pipe similar to the others. He had such a trap made, and was very pleased to find it answer his expectations in every respect. In it he still retained the dome of the "outgo" as in the ᔓ. He had subjected this new form of trap to the most severe tests, and found that when it was fully protected by ventilation it was quite safe from waving or syphonage. He had since patented it. With regard to ventilation, to properly ventilate a soil-pipe and trap, careful thought was required. The kind of apparatus, length of soil-pipe and vent-pipe, also the arrangements below the soil-pipe, must all be taken into consideration, because the diameter of pipe which would be ample for one arrangement would be quite inadequate for another. He was very much surprised to hear Mr. Hellyer say that he should be satisfied with a 2-in. vent-pipe, 50 ft. or 60 ft. long, to ventilate a soil-pipe and trap 7 ft. long and open at the foot. He had practically tried such an arrangement fitted with the five traps before mentioned, alternately, and he found that the only trap which would be quite safe under such conditions was the D. The trap which required the most carefully ventilating was the plain round siphon, and that which required the least was the old D. There was, however, a great difference in the effect which ventilation had upon the two traps. With the syphon the water still rushed through, thoroughly cleansing the trap, and leaving it sealed with perfectly clear water, but the D retained more filth when fitted with an air-pipe than without one. He agreed with Mr. Hellyer in condemning the pan-closet, and the outcome of the experience he (the speaker) had gained since abandoning the pan-closet was that the direct-action closets, such as Phillips's "Sanitary," the "Artisan," the "Carmichael," and the "Vortex," were far superior to several of the more costly ones. Such closets, fixed in a proper manner, with suitable ventilation, and with a flush of two gallons delivered in five seconds, were, in his experience, unequalled for cleanliness. With regard to cowls, he had fixed several on soil-pipes and drains at Margate, both in exposed and in sheltered positions, and upon several he had made some careful observations. In one instance he found during a slight shuffy wind that Banner's cowl repeatedly stopped mouth to wind, at which times the smoke with which he was testing it escaped at the foot-vent. In another case he found that after the smoke had ceased to issue from Banner's cowl, it came up again if he removed the cowl, and ceased when he replaced it. He tried that three times with the same results. In both these instances he found the plain open pipe quite as effective as with the cowl,—indeed, more so. From other observations he was convinced that in cases where the ventilation of the soil-pipes and drains was so arranged that it mattered not whether the current of air passed up or down them, open pipes were best. There were, however, places where it was very desirable to, as far as possible, prevent down-draught, and in such cases cowls were sometimes very useful. In conclusion, Mr. Emptage urged upon all connected with the plumbing trade the necessity of giving increased study to the subject, and expressed his thanks to Mr. Ernest Turner for suggesting, to the National Health Society for promoting, and to Mr. Hellyer for delivering, the lectures.

Mr. Robert Smith denied that Mr. Hellyer was correct in his statement that non-society workmen in the plumbing trade were better workmen than society men. Why should they be? Society men had to rely upon themselves and upon the character of their work as much as non-society men. Mr. Hellyer had advocated the granting of certificates of competency to plumbers. Some years ago there was a serious strike and lock-out in the building trade upon the introduction of what was known at the time as the "Document." Such a certificate as was advocated by Mr. Hellyer would be neither more nor less than the "Document" in a new form, and if the suggestion were adopted the working plumber would be entirely in the power and at the mercy of his employer. While there was some truth in Mr. Hellyer's assertion that young plumbers did not always have a proper opportunity of learning their trade when they were apprenticed in small shops, it should not be forgotten that in a small shop an apprentice would have a greater range and variety of work in all branches, whereas in large shops the principle of subdivision of labour was sure to be more or less thoroughly carried out, and the apprentice would most likely be kept almost entirely to that particular branch of work in which he showed most proficiency. He denied that the ᔓ trap was superior to the D trap, and claimed for the latter that if properly made it was self-cleansing. He thought Mr. Hellyer had been unduly severe in his strictures upon the poor working plumber, while he had "let down" Mr. Norman Shaw very gently,—perhaps because Mr. Shaw was an architect for whom Mr. Hellyer might hope to do work in the future.

The Chairman here intimated that he thought Mr. Smith was going a little wide of the point in imputing personal motives.

Mr. Smith thought he was justified in what he had said. He did not think much of the practicability of Mr. Hellyer's recommendation to use 2½ in. soil-pipes. Although the lectures had been very entertaining, he did not think that the audience had had one particle of knowledge imparted to them from beginning to end ("Oh, oh!" laughter, and hisses). He certainly had not gained one particle of information. The lectures had been of a most rudimentary kind.

Mr. P. J. Davies observed that a great deal had been said by Mr. Hellyer about D-traps being non-cleansing, but he (the speaker) contended that if such traps were properly made they were as much self-cleansing traps as ᔓ or round-pipe traps. Mr. Davies proceeded to show, by experiment, that such matters as pebbles and pocket-handkerchiefs could be washed out of a D-trap by one flush, and he concluded by describing the means of geometrically setting-out an improved form of D-trap contrived by him. The improvement consists, first, in making the "band" of a width not exceeding that of the outside of the dip, the cheeks being only so far apart as just to admit the dip-pipe between them. Secondly, the improvement consists in making the "outgo" of the cheeks of such a shape as will most readily facilitate the passage of the contents of the trap outward over the "band."

Mr. T. H. Court said that, as a practical working foreman of plumbers, he was prepared to say that some of the statements contained in Mr. Hellyer's lectures were calculated to do harm to young plumbers; for instance, the advice to the workman to provide himself or to burden his "mate" with two pots of solder, one to make underhand joints, and the other for general work. If a workman asked him for two solder-pots he should probably give him his ticket to get his money and go off the job. Then Mr. Hellyer had recommended the workman to dilute his solder by putting metal into it. That was very bad advice to give to young plumbers. Every working plumber ought to know without very much testing whether a bar of solder was fit for use or not; if he did not he certainly had not learnt the art of making his solder. He was surprised that Mr. Hellyer had not given some instruction on that point, and that he had not described the way of telling when the solder got foul and the manner of cleansing it. As to joints, Mr. Hellyer had recommended long ones, which were thought by some to be better in appearance than short ones, and to have less tendency to "sweat" because they were wiped cleaner than short ones. But the tendency to sweat could be obviated equally well by bright as by over-cast joints. He did not agree with Mr. Hellyer in saying that ᔓ traps were less liable to "fur" and more self-cleansing than D-traps. Mr. Hellyer had strongly condemned the journeyman plumber for defective work, the blame of which should frequently rest upon architects and others. As foreman of a job, he (the speaker) once had put into his hand a specification in which it was provided that a ¾-in. service-pipe should be used for the supply of four urinals, four closets, three lavatories, two sinks, and a bath (!). He condemned that arrangement as inadequate, and got a clerk of works to represent its inadequacy to the architect; but he was told in reply to follow the specification. The result was that in less than twelve months the whole of the sanitary arrangements were out of order, and a sanitary engineer was called in to put them right. He thought Mr. Hellyer was inconsistent in condemning the pan-closet and yet continuing to supply it. He (the speaker) had had many of them taken out, and when asked what should be done with them, he had always said, "Smash 'em up, and throw 'em on the heap, for they are a disgrace to any one who fixes 'em!"

Mr. W. P. Buchan (of Glasgow) said he had not had the privilege of hearing Mr. Hellyer's lectures, but he was happy to have had the opportunity of reading the reports of them, and he thought very highly of them, notwithstanding the criticisms which he had heard from previous speakers. So far as he could judge from the lectures, as published, he approved of almost everything that Mr. Hellyer had said. He (Mr. Buchan) was at a loss to understand the favour in which the D-trap seemed to be held by some of the speakers, and their prejudice against the syphon-trap. Glasgow was no inconsiderable city, and a great deal of good plumbing work was to be found there; yet, as a Glasgow-bred plumber of thirty years' experience, he never remembered seeing a D-trap used there. All the Glasgow plumbing was done

* For reports of the lectures see the *Builder*, vol. xl., pp. 651, 711, 775; and current vol. pp. 27, 87, 185.

with syphon traps, and syphonage was easily preventible by means of ventilation. It seemed to be forgotten that the ventilating pipe to a trap, if properly made and fixed, killed two birds with one stone, so to speak, for it prevented syphonage, and at the same time prevented the accumulation of foul gases, which would eat away the lead unless carried off. Mr. Davies's experiments with his D-trap were not to his (the speaker's) mind altogether conclusive, for pebbles and pocket-handkerchiefs could be more easily cleared out of a trap than urinary matter and flocculent particles of fæces. Much as was to be said against the D-trap, however, it was far safer to use it than to use a trapless closet. Where illness resulting in death arose from the use of trapless closets, the fixers of them ought to be found guilty of manslaughter. He thought that no one could defend the use of trapless closets upon any scientific or hygienic ground. Pan-closets were bad enough, but where they could not be removed, their evils could be mitigated by ventilating the containers, but with two pipes. While some architects were not blameless for bad plumbing, there were others who had done a great deal to promote good work. There were, he knew, many workmen in the trade who were only partially competent, but Mr. Hellyer's lectures were part of a movement designed to help every working plumber to become a first-class workman. He considered that plumbing was the leading trade connected with building, and that plumbers ought to be the best paid workmen in the building trade. Upon the working plumber largely depended the health of many a household, and as he was often sent to do work without being supervised by a foreman, he should, when of proved competency and reliability, be remunerated for his work with some regard to the responsibility of his position.

Mr. J. Vance said that sometimes when a working plumber who understood his business ventured to point out a defect or a bad arrangement in plumbing work proposed to be done, he was told, by architect or proprietor, as the case might be, "Do as you are told; you are not paid for knowing anything about it, you are paid for doing the work according to instructions!" Personally he felt very much indebted to Mr. Hellyer for his lectures. He had only to say, in conclusion, that when architects or sanitary engineers came on a job to give instructions as to plumbing, they should see the plumber himself, and not give their instructions to the general foreman of works, who most likely knew nothing of plumbing work, and would therefore be unable to clearly explain their wishes. Instead of allowing their instructions about plumbing to be conveyed secondhand, architects and sanitary engineers would do well to see the plumber himself.

Mr. S. Douglass Scoffern said he had not had the advantage of hearing Mr. Hellyer's lectures, which he was sure were of great practical value, but he wished to direct attention to the grave responsibility incurred by partially-instructed tradesmen who arrogated to themselves, without any proper warrant, the title of sanitary, gas, or hot-water engineer, and sometimes all combined. Such pretensions deluded the public, who, by confiding in such men, often incurred disaster. He cited last winter's experience of frozen water-pipes and fatal explosions of kitchen boilers in proof of the danger of employing incompetent men.

Mr. H. H. Collins said that as so much had been said in condemnation of trapless closets, he felt bound to say that one which he had had in use for several years had answered admirably. A good trapless closet had much to recommend it if properly situated and fixed. Of course, if placed in close proximity to, or in absolute conjunction with, a sewer, it would be a most objectionable appliance to use. He wished to say, in reference to what had been said about architects' neglect or ignorance of sanitary details, that very often an architect was no more able to help himself against the stupidity or obstinacy of his client than a tradesman or workman was able to set at nought the instructions of his employer. It was obviously to the interest of the architect to make his buildings healthy; for, if he did not, the sanitary work of houses would pass into the hands of a class of gentlemen called "specialists." It should be remembered that all tradesmen had not established themselves as firmly as Mr. Hellyer, and that all architects did not occupy the proud position of Mr. Norman Shaw. It was not every tradesman nor every architect who could afford to say, "If you won't have the work carried out as I say it ought to be done, I won't undertake it." To an ordinary tradesman or architect the reply would be, "Very well; I will go elsewhere!" Thus to be too high-minded would be, in many cases, to starve. The architect who paid due regard to the most important branches of his work, viz.,—those relating to construction and sanitation, would not spend a lot of his client's money in decorative work to the neglect of sanitary conditions. Personally, he felt deeply indebted to Mr. Hellyer for what he had done, not only by these lectures, but by his writings, to improve the sanitary condition of houses. He was sorry for the speaker who had said he had not gained one particle of information from Mr. Hellyer's lectures, for Dr. Johnson told us that we could learn something even from a fool.

Mr. Lammas urged the formation of an institution for the encouragement, protection, and advancement of the plumbing trade,—a place where the members could meet to read, think, and discuss methods and principles of work, and including, if possible, a small workshop, where the members could put their ideas into execution and to the test of practical experiment. He felt very much indebted to Mr. Hellyer for his lectures.

Mr. Wise supported the suggestion made by the last speaker.

Mr. Savory said that although, perhaps, all that had been said by Mr. Hellyer was not to be taken without question, he had laid down many principles which could not be controverted. It was desirable that the lectures should be published *in extenso* in a cheap form, together with a report of the discussion.

The Chairman, in closing the discussion, said that when Mr. Ernest Turner suggested that the National Health Society should arrange for a course of lectures to working plumbers upon the principles and practice of sanitary plumbing, the initial difficulty was to get a competent lecturer. He knowing the name of Mr. Hellyer as that of the writer of the best practical work on plumbing, invited him to give the lectures, and after consideration he consented to do so, although very much occupied with business and not in the best of health. The lectures had been undertaken by Mr. Hellyer without any remuneration beyond that which was afforded him by the knowledge that they have aroused considerable thought and directed much attention to the subject. The laborious and complete way in which the lectures had been illustrated by diagrams was worthy of all praise. The lectures had been delivered not only in the presence of working plumbers, but in the presence of some of the most skilled and experienced judges of sanitary work in the country, including Mr. Rogers Field, Mr. Ernest Turner, Mr. H. H. Collins, and Mr. Eassie, and he had the authority for saying that those gentlemen regarded Mr. Hellyer's lectures as being of very great value.

Mr. Hellyer, in replying on the discussion, said that he was gratified to find that the remarks made by those who had spoken in the discussion were so largely in favour of the observations he had made in his lectures. With reference to Mr. Emptage's remarks on cowls, he would only say that his experience was that cowls were of advantage: they might, perhaps, add about 10 per cent. to the up-current. He had not made any actual experiments with cowls, but he had found them, in scores of cases, very helpful. Up-currents of air in soil-pipes could generally be increased by the use of proper cowls. With regard to non-society men *versus* society men, considered as workmen, he simply stated his conviction, based on experience, when he said that as a rule non-society men were the best workmen. He wanted the trade societies to be more careful in excluding incompetent men than they had been. He had no more feeling against society men than against non-society men, and had good workmen belonging to both classes in his employ. He was very glad if, as a result of his lectures, Mr. Davies had been able to improve the D-trap, but he (Mr. Hellyer) like a previous speaker, could not see the conclusiveness of the experiments which had been made with Mr. Davies's trap. He challenged the accuracy of Mr. Court's statement that anything said by him in the course of these lectures was calculated to do harm to young plumbers. With regard to using two pots of solder, he simply recommended that in large buildings or jobs two pots of solder should be in use, one for underhand joints and one for coarser joints, the object being to save time. Time was an important element in work, and as an employer of labour he valued time. It frequently hinged upon time whether a master plumber made profit or no profit on a job. As to pan-closets, he had previously explained that he only supplied them under protest, when there was no help but to use them, as in the circumstances he had mentioned. As a matter-of-fact, irrespective of the job to which he had referred, his firm had almost entirely discarded their manufacture and use, and had not supplied more than thirty during the last three years. On all their circulars it was expressly stated beneath the illustration of the pan-closet that it was not an appliance to be recommended. He was gratified that Mr. Buchan should have supported by the weight of his experience what he (the lecturer) had said, for Mr. Buchan was well known throughout the country. Notwithstanding what Mr. Collins had said as to trapless closets, he (the lecturer) still stood by his condemnation of them. In conclusion, Mr. Hellyer said he looked upon sanitary plumbing as an important branch of Preventive Medicine, and, therefore, he regarded the efforts which were being made by members of the medical profession to render it more common as most disinterested and praiseworthy.

After some questions as to whether the specimens of plumbers' work exhibited at the recent Sanitary Exhibition could compete for the National Health Society's prizes (to which the chairman replied in the affirmative), the meeting closed with thanks to Mr. Hellyer and the chairman.

THE ST. JOHN AMBULANCE ASSOCIATION.

On Saturday last, the interesting and instructive Medical and Sanitary Exhibition, which a large number of the professional and outside public owe to the energy of the authorities of the Parkes Museum of Hygiene, was brought to a close, after a highly-successful and only too short a period, by a "demonstration," so the official programme had it, of the pupils of the St. John Ambulance Association, a demonstration illustrating the methods by which hasty and ready aid can be afforded to the wounded and injured in any of the sad accidents which unfortunately so frequently occur.

We specially notice this closing feature of the Exhibition, not alone on the score of its forming one of the features of an exhibition in the aims of which so many of our readers are interested, but with a view to drawing attention,—as we hope to do more fully at a later date,—to the praiseworthy aims of the Ambulance Association, established now some four years since by the Order of St. John of Jerusalem in England, "for the purpose of disseminating general information as to the preliminary treatment of the sick and injured, among all classes of society."

To the readers of any widely-circulated journal attention drawn to an association with such aims would be interesting, but to the readers of the *Builder* the objects of the St. John Ambulance Association are, we feel sure, of particular importance. Accidents, and unavoidable accidents, so frequently happen among those employed in the building and kindred trades that some knowledge of the treatment necessary for the wounded, in the first place, would be of the utmost service in cases of emergency. The series of experiments offered to the public on Saturday last was typical of the accidents that are daily likely to occur; eight different features formed the programme, cases illustrating first aid to be rendered to the injured by civilians (male and female) after railway and other accidents; methods of lifting and carrying the injured; the use of the stretcher; case of gunshot wound to the right thigh breaking the bone; case of both legs broken below the knees by a gunpowder explosion; right hand crushed by machinery accident, with severe arterial bleeding; left foot shot off, with severe arterial bleeding; man found in the streets in a state of insensibility, with a severe wound in the head; and finally the different ways in which a man can help a wounded comrade to reach home. In all these cases aiders and fictitious wounded were ably personated by a number of policemen, civilians, volunteers, and members of the regular army. Great interest, as may be imagined, was evinced by the large crowd collected in the conservatory of the Horticultural Society's Garden to witness the interesting and instructive

"demonstration," the chief and most useful lesson borne away from which by the uninitiated should, we believe, be considered to be that in cases of accident presence of mind and very simple apparatus, not necessarily surgical, are amply sufficient in accidents to afford the first aid to the injured; walking-sticks, umbrellas, bayonets, swords, sheaths, policemen's truncheons, straps, handkerchiefs, scarves, are materials that can be found at hand in all emergencies, and serve admirably at a pinch all purposes of temporary splints and other scientific apparatus.*

We learn that in the four years of its existence, the Ambulance Association has awarded no fewer than 30,000 certificates of proficiency in the admirable course of instruction it affords to persons of both sexes and of every rank of life.

How often do we admire the presence of mind that is displayed by workmen whenever a serious accident takes place in the workshop, but how much more often have we to regret the absence of the knowledge of the precise manner in which immediately to treat a case of fracture or severe bleeding, and how still more often have we to deplore the absence of those who have the slightest conception of what to do in a case of emergency? It is this knowledge, so necessary to aid the professional skill, which the St. John Ambulance Association is desirous to spread among the public.

The Medical and Sanitary Exhibition organised by the Committee of the Parkes Museum was open for the last time on Saturday, August 13th, when the number of visitors, exclusive of season-ticket holders, was 1,221, making a total of 24,333 visitors in the four weeks during which the Exhibition has been open, allowing only for one visit by each season-ticket holder. During the day, the Secretary, Mr. Mark Judge, visited the different exhibitors for the purpose of ascertaining their opinion as to the success of the Exhibition. The exhibitors generally expressed themselves as well satisfied with the result, some going so far as to say that they had done an exceptional amount of business, owing to the fact that a very large proportion of the visitors had been either medical men, architects, or engineers. The representatives of the exhibitors, who have been in daily attendance during the Exhibition, marked their appreciation of the arrangements made for their convenience, by presenting, on Saturday, a small purse of gold to the Superintendent, Mr. Smithson.

ARCHITECTS' CHARGES.

FLOATING A COMPANY.

An arbitration case, which involved several important points as affecting architects' charges, was concluded at the Institution of Surveyors on Friday, the 5th inst., after having occupied two days. The claimant, Mr. Paraire, sought to recover 3,000*l.* for preparing plans, obtaining an estimate for the Alcazar, Leicester-square, and for negotiating for financing the company.

Mr. Glynn was counsel for the claimant. Mr. Winch and Mr. A. Ward appeared for the Alcazar Company. Mr. John Whichcord, past-president of the Royal Institute of British Architects, is the arbitrator.

Mr. Paraire stated the nature of the work done, and Mr. Allbutt, a financier, described the progress which was made in financing the company when the building project was abandoned. The nature of the case will be gathered from the counsel's speeches. It was agreed not to call any architects as witnesses to the custom of the profession, the arbitrator himself being pre-eminently qualified to judge upon points of practice and the reasonableness of the charges. Mr. Glynn, however, read a letter from Mr. Cates, who was unable to be present, stating that he considered the amount claimed by Mr. Paraire to be fair and reasonable; and though the urgency of the company prevented the completion of the work, it involved more cost to Mr. Paraire than if it had been carried out in the usual way. The object was to obtain a *bonâ fide* tender, and that Mr. Paraire procured, and his claim to remuneration for it seemed perfectly clear. Mr. Glynn further stated that he should have called Professor Roger Smith, whose evidence would have been to the same effect.

Mr. Ward said his evidence would, on the contrary, have been that these charges were four times too much.

Mr. Glynn remarked that Prof. Smith took 2½ per cent. instead of 3 per cent.; and he had the Professor and another architect present to prove the facts, but he agreed to leave it in the arbitrator's hands without calling them; but he wished to say that the evidence he could tender would have struck him with astonishment.

Mr. Whichcord said he should feel perfectly at liberty to call upon any one of the witnesses on either side to come to him afterwards if he thought it necessary.

The counsel on both sides agreed that this might be done.

Mr. Glynn called the surveyor who took out the quantities.

Mr. Stephen B. Wilson, surveyor, 27, Walbrook, stated that he prepared the quantities as produced for the purpose of obtaining a builder's estimate. He himself prepared an estimate. It was an approximate sum arrived at by comparing this with other similar buildings. Mr. Paraire gave him the drawings which had been put in, and likewise attended him to explain the way in which he wished the works to be done. The quantities were not taken out in detail. He had previously made an estimate for the Holborn, and also for the Horseshoe. He took generally the quantities for the brickwork, the slating, the floors, and the main items; and he made a comparison between these and the other buildings which he had named. He took the cube of the several buildings, and then he added to or deducted from it, as the case might be. He formed that into a bill, and the result was the estimate now produced, 65,000*l.*, and a builder subsequently accepted that price. He communicated with Messrs. Green & King, builders, and saw one of them at Mr. Blair's, and explained the way in which he had arrived at the estimate. After they had gone into the particulars, Mr. King said he should be happy to give a tender if witness would write him a letter naming the approximate quantities. He wrote a letter to the firm on the 7th of January, 1879.

Mr. Ward remarked that that letter was not strictly evidence, but he should not object to it if the arbitrator wished it to be put in.

The arbitrator observed that Messrs. Green & King were a link in the chain, and he thought it was quite relevant to ascertain what took place between them and this witness.

Witness stated that he took the superficial quantities of the roofs, floors, and galleries, and he deduced the prices from the other buildings. The letter of the 7th of January was then put in. In it he wrote, "I approximately estimate the structural cost as follows:" and then gave the details. Messrs. Green & King in their reply said,—"After going into the probable cost we are of opinion that the structure can be built for the sum of 65,000*l.*"

Mr. Ward.—Is the witness not suing the company for the value of his work in preparing these estimates?

Witness.—I am.

Mr. Ward.—Then we shall in all probability meet again upon that question.

Examination continued.—He afterwards prepared a schedule of prices. The schedule was put in, and was dated September, 1879. He consulted Mr. Paraire in the ordinary way. He afterwards attended before the directors with that schedule of prices, and they were approved of generally. They went through them item by item, and Mr. Wingfield, one of the directors, said he knew as much about building and the price of a rod of brickwork as any one in London.

Mr. Glynn intimated that that concluded the case for the claimant, and before proceeding to sum up the evidence, he remarked that though his learned friend, Mr. Ward, seemed to think that in the course of the hearing he had cast some reflections on the directors of the company, nothing was really further from his thoughts, and he unconditionally withdrew anything that could be so construed. There was a noble lord on the board, and he was rather anxious to know what learned lords knew about these things; and, of course, the directors looked after their fees; but that was only what everybody did after having done his work. Mr. Paraire, in working for this company had a great many masters, and he appeared to have done his work to the satisfaction of most of them; and it was important to notice what they wished to be done and what they determined to build. Mr. Paraire was appointed the architect by resolution, and in pursuance of that resolution he did this work. There were certain preliminary services, which were not part of the work of the architect, and for these he claimed 82*l.* 10*s.* This included a structural plan, which, by his advice, was put upon the prospectus of the company; and also charges for attendance at several of the directors' meetings. For all such preliminary services it was well known that the solicitors, the surveyors, the directors, and the promoters, expected to be paid fairly, and more than fairly, because it was disagreeable work, and it was uncertain whether the company would float. The claim in connexion with the application for a licence was virtually admitted. The next item was 1,625*l.*, being 2½ per cent. on the tender of 65,000*l.* which Messrs. Green & King said they were prepared to give. He did not care whether the arbitrator was of opinion that they were prepared to carry that out or not. Mr. Cates and all the witnesses were of opinion that it did not make any difference, as regarded the quantities, whether the tender was accepted or not. Mr. Paraire had done his work, and was entitled to the scale of payment laid down by the Institute of Architects. If the directors had not got a tender, it was their fault. They had chosen to form a ground-rent, and not build the Alcazar at all; but they could not avail themselves of that to refuse to pay these charges. It was exactly the same as an ordinary case of selling property. If you bring buyer and seller together, and the seller then said, "I will employ you no longer; I will not sell," the person who introduced the buyer to the seller is entitled to his commission. They were dealing with professional gentlemen, whose charges were not to be measured in the way that the Alcazar Company seemed to think they should be measured. It was not a mere question of time, as with a cabman, nor of the cost of paper, paint, or pencils. He was entitled to fair remuneration, according to the recognised scale in the profession, and that amounted to 1,625*l.* The next item was 325*l.* for getting the builders' tender. Mr. Paraire was instructed by the Board to assist in preparing the quantities which it was desired to get out in a great hurry. For these services, which had nothing to do with the other work, he charged according to scale, and there was no evidence impugning the accuracy of the claim. The only other item in dispute was 68*l.*, for obtaining the necessary capital. Mr. Paraire stated that he had bargained with the directors that for financing the company he was to receive 1½ per cent. on the amount required for the building, and that he succeeded was not refuted, though Mr. Allbutt was cross-examined for two hours and a half. There was a resolution of the company showing that the directors very well knew he was endeavouring to get the money, and if he had not been able to get it he was entitled to fair remuneration for the work he did. But his contention was that he did get it. Mr. Allbutt, a financier engaged by Messrs. Boston & Co., for the purpose of carrying this matter out, stated that he was prepared to provide the money if the Alcazar Company had gone on; and Mr. Paraire having introduced Messrs. Bolton & Co. to the directors was entitled to his commission of 1½ per cent. Mr. Paraire had been kept out of his money for a very considerable time, and he claimed interest, which the arbitrator was entitled to give on the amount which he might award. The very small sum of 1,000*l.* was ordered to be paid into court by the Master, and the defendants would have to pay interest upon that as well as on the amount that was due, because it was only paid into court as security for the claim, and they would otherwise not have been entitled to bring this action at all. In conclusion, Mr. Glynn thanked the arbitrator for the very great attention he had given to this matter, and for his kindness in consulting the convenience of the counsel engaged.

Mr. Winch, replying on behalf of the Alcazar Company, stated that, when the directors had this bill before them, they consulted gentlemen of Mr. Paraire's own profession, and obtained from them a decided opinion that it was four times as much as it ought to be, and therefore they were bound to dispute it. But that they did not wish to do so unfairly was shown by their agreeing to send it to one who stood at the top of Mr. Paraire's own profession to be decided. There were twenty guineas for services before the company was formed, about which he would not trouble. Then there were thirty-six guineas for the large coloured elevation, which was before them, as to which the arbitrator could form an opinion. The substantial part or claim was the percentages. Now, 2½ per cent., if justifiable at all, was justified upon the basis of a document very well known,—the professional charges,—which said that if an architect had drawn out plans complete, with elevations, sections, and specifications, the charge was 2½ per cent. commission upon the estimated cost, and if he had procured tenders the charge was ½ per cent. extra. But Mr. Paraire's own evidence showed that he had not brought himself within that rule. There was no specification, or drawings, and no plan of the roof. Therefore the claim must fall back upon work and labour. Of course, as the arbitrator had intimated, if a man was asked to design a building, and by a stroke of genius immediately sketched off the key-note of the whole thing, it might be worth 1,000*l.*, but that was a gift which ordinary men did not possess. If, however, the arbitrator saw in this design an unusual display of genius, by all means the claimant must have a due sum for it. He would take Mr. Paraire's own figures (5*l.* a day) for his ordinary work. Allowing these plans to have taken eight weeks, and including Sundays, it would give 280*l.* The addition to be made for genius he would leave to the arbitrator, merely remarking that it was a building which was not put up, and did not succeed. The design was not so brilliant as to induce the public to come forward and subscribe 65,000*l.* He did not say that a man who had to use his brains should only be paid for mere mechanical labour; but he should be very much astonished if the arbitrator put the value on the plaintiff's brains in preparing these plans at 1,400*l.* Then as to the claim for 325*l.* That was put in the summary account as ½ per cent. for getting a tender; but as his friend, Mr. Glynn, could not argue that there was a tender here, it was now put on the ground that Mr. Paraire was obliged to give the surveyor an immense amount of assistance in order that he might be able to get out the quantities. But if he did, it was all thrown away, as the surveyor did not pay much attention to it. He squared the floors and the roof, and then got hold of another plan to compare the figures with, and said that was near enough. Messrs. Green & King's letter was no tender, but simply an expression of opinion that the work could be done for a certain sum. It was an estimate obtained to put before the shareholders to give them some sort of opinion what the building would cost, and that some sort of opinion was 65,000*l.*; but whether it could be erected for that was very shadowy. They would agree to do it at Laxton's prices, and well they might, seeing that they were top prices, and tenders were always a percentage under them. In giving the surveyor his assistance, Mr. Paraire was occupied five or six days, and surely this was mechanical work, to be paid for at his own valuation, 5*l.* a day. Then came the last item, 680*l.*, for financing, and the question was whether the plaintiff did find any

* We remember a distinguished painter once having been able at an emergency to successfully set and bind up a broken arm, with a splint made of an old palette, a number of paint-brushes, and his painting-rag; on the arrival of the doctor nothing more was found to be necessary.

body who was willing to advance the money. Now, Mr. Allbutt's offer was that he was prepared at once to proceed with the building, provided the undertaking was handed over for reconstruction, three directors nominated by the company to take seats on the reconstructed board along with three appointed by the capitalists, but no liability could be entertained beyond a mortgage of 30,000*l.* The directors would have accepted even this modified contract conditionally on having 5,000*l.* down, but the parties could not agree. He therefore submitted that Mr. Parsire had entirely failed to obtain the 65,000*l.*, or an offer of it. Where a man had made a specific contract of this sort, he either got all his commission or nothing; but the directors did not wish him to be without remuneration, and would give him 5*l.* a day for the time he was engaged in the matter. The Company, he was glad to say, were well able to pay whatever might be awarded, but the directors felt they were not justified in drawing a cheque for this 3,000*l.*, and they had adopted the only course a body of gentlemen ought to do, by submitting it to arbitration.

This terminated the proceedings, the Arbitrator taking time to consider his award, and if necessary, to consult professional gentlemen named by either side.

WILTSHIRE ARCHÆOLOGICAL SOCIETY.

STONEHENGE.

The annual meeting of this Society was held last week at Bradford-on-Avon. The general meeting of members was held on Tuesday in the Town-hall, Sir Charles Hobhouse, bart., presiding.

The report read by the secretary (Rev. A. C. Smith) showed that the Society, both numerically and financially, was in a flourishing state; but during the past year the Association had lost very many useful and worthy members. The attention of the committee had been directed to the present condition of Stonehenge, some of the stones of which were leaning at such an angle as to render their fall at no very remote period a certainty. They had, therefore, communicated with the Society of Antiquaries, who had appointed a committee to report as to what steps should be taken in the matter, and should they deem that immediate steps were necessary, it would remain to approach the owner of the property and ask his consent to allow the necessary operations to be performed.

On the motion of the Rev. W. C. Kis, seconded by Mr. T. B. Saunders, the report was adopted.

Mr. Saunders deprecated any attempt to restore Stonehenge, remarking that such a proceeding would result in having Stonehenge such as it was never seen by the Druids or those before them.

The officers of the Society having been re-elected, with Mr. H. E. Medlicott, of Potterne, appointed as general secretary, in place of Mr. C. H. Talbot,

Sir Charles Hobhouse delivered an interesting inaugural address. He said he felt himself to be an absolute tyro in archæology. Most of his life had been spent in India, and but for a train of circumstances which occurred soon after his residence in Wiltshire he would never have acquired a taste for the study of the subject. After he had been poring over the parish registers or some old terrier of the days of Elizabeth, he was inclined to ask of the art of archæology,—*cui bono?*—What good is it? He supposed he need not answer that question in such an assembly; but still, it seemed to him that even the enemies of archæology, if they would consider a little, would find that they themselves spent a great part of their time in the midst of that study which they affected to despise. The life of a man was spent in three worlds,—the past, the present, and the future,—and all the study of the past history, biography, &c., was really the study of archæology. The wants of every-day life were to a great extent dependent upon that study. Any one choosing a house in the country or the suburbs of London would not prefer a house in the modern style of architecture,—that meant a square door in the centre, two square windows on either side of the door, and three square windows above. They would rather choose a house built in the Elizabethan or Hanoverian style, making use of modern appliances for internal comfort. But the taste for art in architecture was growing out of the increasing love for archæology. The comparison between a modern building and one the produce of a remote antiquity showed that there was still much to be learnt. When travelling in India he was struck with the wonderfully large water-tanks, the sides of which were made with huge blocks of stone laid one on another, without any kind of cement or clamps. No repairs, he was told, were ever needed; how was it that in the case of modern reservoirs they did not profit by the lessons of antiquity? Sir Charles then described the beauties of the Hindoo temple at Agra, and the emblematical royalty of Akbar's camp at Futtehpore Sikri, each of which was, thanks to the climate, in almost as good a condition as when constructed. He did not mean to say that we should imitate those things, but he thought they taught us moderns many a lesson in the science of architecture. He further described the wonders of the rock-cut temples in Western India. Archæology, he said, was the history of the one of our rural parishes, and in miniature the history of the whole country. To illustrate this he gave the history of his own parish (Monckton Farleigh) from the time of the compiling of the Domesday-book, and traced the analogy between it and the ecclesiastical and general history of the changes and development of the country.

The Rev. Canon Jackson, referring to the "restoration" of Stonehenge, said that all that was intended to be done was to lift up the trilithon which had fallen, and the proper place of which was well known.

The Rev. Canon Jones gave a lengthy account of the ecclesiastical history of the town of Bradford-on-Avon, and the various churches and other objects of archæological interest which it contained, especially the Saxon church recently discovered. In the afternoon the members thoroughly examined the parish church, the interesting old Saxon chapel, the Church-house, the Shambles, the old Market-place, the site of St. Olave's Chapel, Kingston House, the chapel on the Town-bridge, the chapel and almshouses of St. Katharine, Tithe-barn, St. Mary's Chapel, and Christ Church, all of which were very ably described, and their leading points of interest were shown by the Rev. Canon Jones.

After the town had been thoroughly inspected, dinner was provided at the Swan Hotel, Sir Charles Hobhouse, bart., presiding; and, subsequently, a *conversazione* was held in the Town-hall.

The meeting was continued on Wednesday. The members started in carriages from the Town-hall, the first halt being made at Westwood, where the interesting little church was described by the Rev. Canon Jones, who traced the history of the parish from the early part of the eleventh century. He called particular attention to the remains of stained-glass windows. The next halt was at Stowford Manor-house, which was thoroughly inspected by the visitors, and described by Canon Jones. This old Elizabethan house is now in the occupation of Mr. James Wadman. The next halt was made at Farleigh Castle, the ancient residence of the Hungerford family. The old ruins and chapel were inspected by the party, but no description was attempted, as the time pressed. The next halt was made at Beckington, where luncheon was partaken of, after which the party proceeded to Seymour-court, and thence to Road Church. North Bradley Church was examined, and the party returned to Bradford about six o'clock. In the evening a *conversazione* was held in the Town-hall, at which an interesting paper was read by Sir Charles Hobhouse, bart., on "Some Account of Monckton Farleigh," and one by Mr. F. Shum, F.S.A., on "Some Notes on Gainsborough, and his connexion with Bradford."

On Thursday morning, the members of the Society met at the Town-hall, at ten o'clock, and proceeded in breaks to Holt. Thence they went to Monckton Manor House, and thence to Broughton Gifford Church. They next visited Great Chalfield Manor House, where the Rev. Prebendary Jones acted as *cicerone*, and explained that this was one of the finest manor-houses in England, and was built by Sir Thos. Tropenell, who died in 1490. In the little church adjoining the manor-house is a chapel built by Sir Thomas Tropenell, and at one time it was enclosed by a carved stone screen, which is now removed so as to form an enclosure to the church. The walls of the chapel, which are now only whitewashed, were once decorated with paintings representing some of the saints, and it was stated that they were whitewashed by order of a previous vicar, who found that the congregation paid more attention to the pictures than to his sermon! The outlines and some of the colourings of the figures are still visible, but it is the intention of the present owner of the property (Mr. Fuller, of Neston Park) to endeavour to restore them. The arms of the Tropenell (now known as the Trapnell) family are emblazoned on the cornice of the stone screen and at the intersections of the roof of the chapel, showing the quarterings with the great families in marriage,—the Percys, the Ludlows, and the Roches. Luncheon was given in a large tent to about 150 guests, when the president of the Society (Sir Charles Hobhouse) expressed the thanks of those present to Mr. Fuller for his kind and liberal hospitality on the occasion, stating that it was about twenty-four years since the visit of the Society to this ancient and interesting manor.

The party visited other places of interest, and in the evening the meeting was brought to a close.

FROM ABROAD.

Monument to Maximilian, Mexico.—A decree has been issued by the State Government of Queretaro, in Mexico, determining upon the erection of a monument to commemorate the execution of the Emperor Maximilian and the Generals Miramon and Mejia, the monument to consist of truncated pyramids.

International Exhibition, Shanghae.—It is reported that the year 1883 will witness an international exhibition in Shanghae, now in contemplation.

Archæological Discoveries, Carthage and Utica.—M. Herrison, who is said to have made important archæological discoveries in Carthage and Utica, is about to publish an interesting work on the subject. He arrived in Paris lately.

Beneck Prize.—The University of Goettingue has announced that the Beneck prize will be awarded to the best essay on the following subject, to be written in German, Latin, French, or English, viz.—"A general exposition of the development of the Italian people, entering into details to show what the plastic arts and the drawing of the Italians owe to non-Italian nations." The essays must be sent in before the 31st of August, 1883.

A BUILDER'S CLAIM.
WRITTEN ORDERS AND CERTIFICATES.

GOODMAN *v.* LAYBORN.

This case was argued on August 1st, before a Divisional Court, consisting of Mr. Justice Grove and Mr. Justice Lindley, and came before the Court on motion for judgment on the report of an official referee. Mr. E. S. Roscoe represented the plaintiff, the builder, and Mr. Woolf the defendant, the employer, a gentleman residing at Ramsgate. It appeared from the statements of counsel that this claim arose out of two contracts, one to complete certain houses at Herne Bay, and the other to alter a house at Ramsgate; there was also a third claim by the plaintiff for a small sum for other work, in respect of which the official referee awarded 8*l.*, and upon which no dispute arose. In the case of the Herne Bay contract the referee had awarded the sum of 27*l.* odd for extras, and to the finding the defendant took exception, on the ground that by the terms of the contract an order in writing should have been given, and, this not having been done, that the builder could recover nothing. It was contended by the plaintiff that the words of the contract, which were that no extra work should begin without a written order, referred only to the commencement of the work, and were not a condition precedent to payment for work actually ordered and done. As regarded the Ramsgate contract, there had also been no written orders, but the architect had received the builder's account for extras, had placed his own figures in the margin, and had thereby largely reduced the builder's claim. At the foot he had placed the amount of his calculation, and had before signing his name (W. G. Osborne) written "Balance due as per conditions, 125*l.*" It was contended by the plaintiff that this was a final decision of the architect, and that though the word "certificate" was placed in the contract, yet that in effect all that was required was a final decision, which this was. The employer also claimed penalties against the builder for the non-completion of the work within the time specified in the contract. The Court, in giving judgment, disallowed the sum claimed for the Herne Bay extras, on the ground that by the contract written orders were necessary, and that, no certificate having been given by the architect, their absence was a bar to the recovery of any sum whatever by the builder. As regarded the Ramsgate contract, they held that no particular form of document was necessary for a final certificate, as required by the contract, so long as it showed the final decision of the archi-

tect, and they considered that this document did away with the necessity for written orders, and they upheld the report as to the sum awarded for extras in respect of this contract. As to the penalties, the Court desired a further report from the referee as to the circumstances under which the delay in completing the houses took place, and referred the report back to the referee for further information on this point.

[This case clearly is another example of the stupidity of builders in not sticking to the terms of their contracts. They should refuse to do extra work without written orders, and should not trust to the good nature of their employers, which is not to be relied on. It is clear, too, that architects should always give written orders without being asked to do so by the builder; they thereby save their employers immense annoyance and expense, and, indeed, are only fulfilling their plain duty. But it is astonishing how they continue to give verbal orders for extras when the contract plainly requires them to be in writing.]

THE STREETS OF BERLIN.

Owing to the execution of the new system of sewers in the German capital, the length of the principal streets of the city has recently been exactly measured. The celebrated avenue Unter den Linden has a length of 1,350 mètres, or less than seven furlongs; Wilhelm-street, the head-quarters of the Ministries, is 2,000 mètres long; while the well-known Friedrichs Strasse has a length of 3,060 mètres, or not far short of two miles. Of the streets which extend beyond the limits of the city proper, Müller-strasse has a length of 3,600 mètres, Kurfürstendamm 3,925, See-strasse 4,085, Kaiserstrasse 4,215 mètres. The longest series of streets running in one continuous line with unbroken rows of houses is that of the Friedrich-strasse, with its continuations the Chaussée and Müller streets, the aggregate length of which is 8,440 mètres, or upwards of five English miles.

ART-UNION OF LONDON EXHIBITION OF PRIZES.

It was a very generally-expressed opinion amongst those who were at the private view in the Art-Union Gallery last week, that the selection of works by the prizeholders showed a great advance on that of former years. We hope that this may be taken as evidence of that improvement in the taste of its members, and that power of discriminating between good and bad works, which it has been the great aim of the Institution to effect. Certainly to those who recollect the time when Mr. Shayer's gipsies and donkeys, and the roast beef and plum pudding of Pidding and Clater entered largely into the annual gathering, the change appears very great.

The most prominent works having already been noticed when reviewing the galleries from which they have been selected, any lengthened notice is unnecessary. Still there are one or two points worthy of mention. We are glad to observe that sixteen works have been chosen from the Royal Albert Hall Gallery. If artists could be induced to send their works to this gallery when they have been accepted at the Royal Academy, but not hung for want of room, as in the case of a considerable number of pictures lately shown here, this would soon become an important exhibition, and artists would find their advantage in it. Amongst the works from the Hall specially worthy of notice are No. 31, "St. Michael's Mount, Cornwall," by Mr. Sydney Hodges; and two landscapes, Nos. 43 and 48, by J. Anderson, admirable for careful execution and finish, and the truthful effect of shadow on the surface of the water.

The work of greatest importance in the gallery is the "At last" of Mr. Arthur Stocks. An old dame has just received a letter from her son, or perhaps grandson, probably announcing that he was on the point of going into action, and now he unexpectedly arrives to "set her heart at rest." It is a work full of sentiment, and well and solidly painted, and it is to be hoped it will find a suitable resting-place in Quebec, whither it is going; it is rather large for a house of ordinary size.

Amongst the water-colours, the principal is "The Loss of the *Revenge*," by Mr. Oswald Brierly, which formed the subject of the engraving given for the past year. For effective treatment and truthful rendering of light and shadow on the surface of water, "The Ferry on the Trath," by Mr. J. J. Curnock is remarkable.

We have already called attention to the exceptionally liberal presentation work prepared for the current year's subscribers,—a series of five plates from Mr. Frith's well-known pictures, "The Road to Ruin."

PATENT RECORD.*

APPLICATIONS FOR LETTERS PATENT.

3,223. T. Barnby, Birmingham. Folding or camp furniture. July 23, 1881.

3,250. D. Grove, Berlin. Steam cooking apparatus. July 25, 1881.

3,261. T. W. Helliwell, Brighouse. Making the glazing of glazed structures impervious to dust, air, and water. July 26, 1881.

3,276. C. E. Bulling, Camden-street. Adjusting the position of swing looking-glasses, sashes, doors, &c. July 26, 1881.

3,303. J. H. Johnson, Lincoln's-inn-fields. Manufacture of artificial stone and marble. (Com. by La Société Anonyme de Certaldo, Paris.) July 28, 1881.

NOTICES TO PROCEED

have been given by the following applicants on the dates named.

July 26, 1881.

1,252. J. W. Lewis, Halifax. Raising and lowering window-sashes, &c. March 22, 1881.

1,277. H. G. Grant, Manchester. Furnaces or stoves. (Com. by A. Prevot, Bergerac, France.) March 23, 1881.

1,327. T. Morgan, Charing-cross. Magazine heating-stove. (Com. by O. Elterich, Nuremberg.) March 24, 1881.

1,483. J. Ingleby, Manchester. Cocks, valves, &c. (Com. by R. Meyer, Breslau.) April 5, 1881.

2,442. J. L. Corbett & W. Lochhead, Glasgow. Taps or valves, &c. June 3, 1881.

July 29, 1881.

1,304. J. Rettie, Hatton-garden. Binding for scaffolding, &c. March 23, 1881.

1,309. A. C. Henderson, Southampton-buildings. Safety wicket and grating for street-doors. (Com. by J. M. A. Montclar, Paris.) March 24, 1881.

ABRIDGMENTS OF SPECIFICATIONS

Published during the Week ending July 30, 1881.

5,293. E. P. Alexander, Southampton-buildings. Furnaces and fire-places.

Instead of the usual fire-bars, rectangular perforated cast-iron gratings are used, which have ribs on them to lift the fuel up and allow the air to have free access. (Com. by C. Nikiphoroff, Paris.) Dec. 17, 1880. Price 6d.

5,295. W. Phillips, Leeds. Window-sashes, &c.

A vertical groove is formed in each sash-stile to admit a round metal rod which is pivoted in the centre of the sash-stile, and so arranged that it may be moved outwards, carrying the rod clear of the groove and into a recess in the pulley-stile, when the sash can be reversed. Dec. 17, 1880. Price 6d.

5,306. T. H. Goodson, Berlin. Automatic apparatus for preventing waste of water in water-closets.

The valve-box contains two check valves; the upper valve's stem buts against the underside of the closet seat. Between the two valves is a pipe leading to an air-vessel. On the seat being depressed the upper valve forces the lower valve on to its seat and prevents any more water passing to the closet basin, but allows it to enter the air-vessel, partly compressing the air. On the seat being raised the upper valve closes the supply-pipe and then raises the lower valve, when the compressed air in the air-vessel forces the water out and flushes the basin. Various modifications are shown. (Com. by H. E. T. Goodson, Berlin.) Dec. 17, 1880. Price 6d.

5,308. J. Wiley, Darlaston. Clips for gutter spouting.

The bar has the two ends bent downwards. A hole is formed near the top of each fork of the clip. The bar is placed in position by pushing each bent end horizontally through the holes, when they fall downwards by their own weight, and the bar cannot be blown or shaken out of its position. Dec. 18, 1880. Price 6d.

5,333. C. R. Stevens, Lewisham. Valves and shafts and caps and cowls for ventilating.

This is an improvement on patent granted on the 13th of December, 1877, in various minute details, which are shown in forty-two figures. Dec. 20, 1880. Price 10d.

5,356. E. de Pass, Fleet-street. Combined washstand and bath.

A lid is fitted to the top of the bath, hinged at the back in which a washing basin is fitted. (Com. by A. Avon, Paris.) (*Pro. Pro.*) Dec. 21, 1880. Price 2d.

* Compiled by Hart & Co., patent agents, 28, New Bridge-street, E.C.

5,368. J. H. Owen, Dublin. Reversible cresset grate.

The cresset is hung on pivots, and has the front and back formed of bars while the sides are iron plates. Plates are arranged to slide in over the bars. The fresh coal may therefore always be arranged to be beneath the live fire and the smoke is consumed. (*Pro. Pro.*) Dec. 22, 1880. Price 2d.

5,414. A. C. Farrington, Shelfanger. Apparatus for giving alarm and securing doors, windows, &c.

The bolt is forced against a coil-spring. A catch is fitted to draw the bolt in, which, when liberated, is shot forcibly back by the spring, and can strike a gong, &c. (*Pro. Pro.*) Dec. 23, 1880. Price 2d.

5,424. H. Johnson & B. Stuart, Keymer Junction. Apparatus for pressing or moulding bricks.

A box mould is made with its sides and ends hinged, so that when removed from the outer die or box, the brick, &c., can easily be removed. Dec. 24, 1880. Price 6d.

5,439. H. Payton, Birmingham, and W. S. Dackers, Balsall Heath. Attaching door-knobs to their spindles.

The end of the spindle is split longitudinally at opposite sides. The square hole in the bush of the knob is divided by a partition into two parts. When the spindle is passed through the door, the knob is forced on the elastic forked end, which holds it tight. Dec. 24, 1880. Price 6d.

AWARDS TO JOURNEYMEN PLUMBERS.

The following is a list of the awards made in respect of the works sent by journeymen plumbers to the recent Exhibition of Sanitary Appliances at South Kensington. The judges, as appointed by the Committee of the Parkes Museum of Hygiene, were Messrs. John T. Bolding, W. Paton Buchan, A. A. Common, and S. Stevens Hellyer.

Awards of the First Class, for Special Excellence of Workmanship, were given to George Davis, J. W. Hart, George Macfarlane, and G. Taylor. For Excellence of Workmanship to John Wm. Fuller, W. T. Otway, Thomas Sheppard, and J. Vance.

Awards of Merit for Fair Workmanship were given to David W. Buchan, Thomas Cranston, Thomas Harrison, Edward Lyne, James B. Macfarlane, James Wood, John Wyse, and A. J. Nickels.

MONUMENTAL EXHIBITION, LISBON.

An Exhibition of the Monumental Art of Portugal is to be shortly opened in Lisbon. Official intimations have been made to the several civil governors of all the districts, in order that they may invite the municipal councils, parochial Boards, confraternities, and other establishments and corporations of that kingdom, to entrust to the committee appointed for the management of the Exhibition with such objects as may be selected by the agents of that committee out of those they may possess for the said exhibition, on condition of their being returned after its termination.

STRATTON.

Several improvements are being carried out on the estate of the Earl of Northbrook, K.G., at Stratton, near Winchester. The homesteads on some of the farms have been entirely rebuilt on approved principles, and the farm-houses remodelled. Only one pair of cottages has at present been erected; but more are contemplated. The whole of the farm buildings and cottages are built of bricks and local-headed flints pointed with black mortar. The cottages are covered with plain tiles, and the farm-buildings with slates, except those at the East Stratton Farm, which are covered with Poole's patent tiles. The whole has been carried out by local tradesmen from the designs and under the superintendence of Messrs. Raynbird & Sons, surveyors and land agents, of Basingstoke, who are also erecting other homesteads on the estates of Lord Templemore, at Preston Candover, near Alresford; and of Mr. W. W. B. Beach, M.P., of Oakley Hall.

Art Exhibition at Brussels.—The Triennial Exhibition of Painting and Sculpture was opened on Sunday afternoon at the Palace of Fine Arts, in the presence of the King and Queen. The Exhibition, which is large and varied, is reported to maintain the honour of the Belgian school. There are also many pictures from France and Germany.

OBITUARY.

Mr. Selim Rothwell, Artist.—The death of this gentleman was sudden, and is said to have been expedited by his exertions in getting up an exhibition for the benefit of the new infirmary at Bolton. Mr. Rothwell was born in Bolton in 1815. His father, Mr. Edward Rothwell, was a house-painter and decorator. Mr. Selim Rothwell was educated at the Bolton Grammar School, and was afterwards trained in his father's business, being taught the art of drawing at the Mechanics' Institution. He was a pupil of Mr. George Berry, the drawing-master of that town, a man of considerable ability and a friend of the late Charles Swain. On his removal to Manchester, about twenty-five years ago, whilst continuing to practise as a drawing-master, he became in an increasing degree a landscape-painter. The charm of Mr. Rothwell's drawings of the buildings of Italy was widely acknowledged. Brittany and Normandy were also favourite resorts. Besides wielding the brush with skill, Mr. Rothwell was an enthusiast in the use of the etching-needle. He was one of the early members of the Manchester Academy of Fine Arts, and his business capacity and the esteem in which he was held by his colleagues gave him an active part in the management of its affairs, first as a member of the council, and latterly as its literary secretary. In 1877, he printed for private circulation a small volume entitled "Scraps from an Artist's Sketch-book." It contained some of his Continental impressions, and was illustrated by photographs from his drawings.

SURVEYORSHIP ITEMS.

Witney.—A meeting of the Highway Board for the Bampton East Division was held a few days ago for the election of a road surveyor for the district, in the room of Mr. W. A. Richards, resigned. The value of the appointment is 120*l.* There were upwards of thirty candidates, five of whom were selected for final decision. The ultimate result was the election of Mr. Jasper Taylor, inspector of nuisances to the Witney Rural Sanitary Authority. The voting was as follows:—Taylor, 16; Hemmings, 4; Richards, 3; Wells, 0; Bailey, 0.

Horsham.—We see by the report of Special Sessions, held at Horsham on the 23rd ult., that Mr. Charles W. Whitaker, C.E., of 6, Great George-street, Westminster, was elected County Surveyor for West Sussex. Mr. Whitaker is the son of Mr. Thomas Whitaker, late County Surveyor for Devon, and City Surveyor for Exeter, and is carrying out the drainage and waterworks at Budleigh Salterton, drainage of Chard, and other works in the West.

FURTHER SALES OF BUILDING LAND AT STREATHAM, WILLESDEN, AND WOOD-GREEN.

Within the last fortnight there have been several large sales of freehold building land in different parts of the suburbs of London. A few days ago Messrs. Debenham, Tewson, & Co. offered for sale a portion of an estate at Streatham, containing about nine acres, which has been laid out for building upon. The estate is close to Leigham Court-road, and within a few minutes' walk of the Streatham Hill, Tulse Hill, and Lower Norwood Railway Stations, the site commanding some beautiful and extensive views. The several plots have frontages of 25 ft. to a new road called Knollys-road, 50 ft. in width, and from 200 ft. to 250 ft. in depth. The stipulations provide that no house is to be erected on any plot of a less value than 600*l.*, nor within 20 ft. of Knollys-road. No tavern or hotel is to be erected on the estate, and it is also provided that no business whatever is to be carried on on any plot. The sale took place at the Greyhound Inn, Streatham Common, when there was a large attendance, twenty-four plots being disposed of at an average of a little more than 5*l.* per foot frontage, or about 125*l.* each. The entire proceeds of the sale amounted to 3,200*l.*

Messrs. Croucher & Co. offered for sale, at the King's Arms Hotel, Wood-green, a portion of the Alexandra Estate, which was stated to be bounded on two sides by the pleasure-grounds of the Alexandra Palace, with good railway accommodation, the estate being in close proximity to five railway stations. The drainage was said to be constructed on the most approved sanitary principles, and in accordance with the requirements of the local authorities. The several plots have frontages of 20 ft., with a depth of from 100 ft. to 130 ft., and were stated to be suitable for the erection of shops, and other residences. Thirty-five plots were sold at prices ranging from 60*l.* to 75*l.* each, whilst a corner plot, having a frontage to Crescent-road of 110 ft., and to Albert-road of 59 ft., realised 153*l.* The sale altogether produced 2,450*l.*

Messrs. Baker & Son also sold at the Auction Mart, fifteen acres of freehold land in Harrow-road, Willesden, which realised 4,380*l.*

AMERICA.

The *Scientific American* (New York, July 23) devotes half a page to the aqueduct over the Cabin John Creek conveying the Croton water to Washington. This bridge, which is a single span of 220 ft., with a height of 101 ft., is stated to be the largest masonry arch in the world. It seems surprising that a work of such magnitude should not be better known; but the explanation given is that it was completed during the Civil War, and that at the time it was considered unadvisable to draw the enemy's attention to the means by which the capital received its supply of water.

A description is given in this number of the new town which has sprung up a few miles south of Chicago, under the auspices of the Pullman Palace-Car Company. In June last year, the site of what promises to be a large and prosperous community was a broad stretch of prairie; but to-day the town of Pullman presents an appearance superior to that of any manufacturing centre in the States. It contains a handsome railway station, workmen's dwellings, constructed with every consideration for convenience and health,—a park,—beautifully laid out,—a large hotel, market-hall, stores, arcade, &c.; whilst an art-gallery and public library are in course of construction.

"Art on the Stage" is the title of an interesting paper in the supplement of the same date, on scene-painting. The materials used and the system employed in this much-ignored but really important branch of painting are explained at full length; and hints are given for the employment of tin-foil, bronze powders, and leaf-metal, which can hardly fail to be of value to decorators who have to look more to scenic effect than to careful painting for close scrutiny.

GET ORDERS FROM PRINCIPALS.

KAY *v.* ROBERTS.

In the Salford County Court, before Mr. J. A. Russell, Q.C., Mr. Kay, plumber and glazier, Prestwich, sued Mr. C. J. Roberts, solicitor, of Rochdale and Manchester, for 13*l.* odd alleged to be due for work done in the erection of certain cottages at Prestwich. Mr. Bradbury, barrister-at-law, appeared for the plaintiff; and Mr. Hockin for the defendant. It was stated by Mr. Bradbury that in 1879 Mr. Roberts was building seven cottages at Prestwich, that a man named Joseph Buckley was employed by him to superintend their erection, and that Buckley on defendant's behalf applied to plaintiff to tender for certain plumbing and glazing work required to be done. Plaintiff sent in an estimate, which was accepted, and did the work, for which he was paid by the defendant. These particulars were mentioned in order to show that Buckley was evidently defendant's agent in the matter. Subsequently defendant erected six other cottages,—or five and a shop,—at the same place, and in October of last year Buckley came again to plaintiff and asked him to send in a tender for the plumbing and glazing. Plaintiff sent an estimate accordingly to Mr. Roberts, offering to do the work for 16*l.* 10s., and he engaged, if it was determined to make a shop of one of the cottages, to glaze the window for three guineas. Two or three days afterwards Buckley told the plaintiff that Mr. Roberts had accepted the tender and desired him to do the work. Plaintiff did the work, including the glazing of the window for the shop, and he also did certain extras, the charge for which was now in dispute. In the November following plaintiff received 3*l.* on account, and in December 2*l.* additional. On the 27th day of December plaintiff called again on Mr. Robert, for the purpose of receiving another instalment, but did not get one. On the same day, however, defendant wrote to him enclosing a cheque for 8*l.* on account. Plaintiff sent in his account again on March 27, and then for the first time he heard that Mr. Roberts disputed his liability for the work. In a letter which he had written he said that it was Buckley who was to pay, and that at the time he was not a principal in the matter, but the guarantor of Buckley. That, it was contended, was not so. Plaintiff was called, and gave evidence in support of the statement made by the learned counsel. His Honour asked him who gave the orders for the extras. He replied that he received them from Buckley; and in reply to another question, added that Buckley never told him that he had Mr. Roberts's instructions for those extras.

Mr. Hockin put in a document showing that Mr. Roberts had limited his liability to 16*l.* 10s. which had been paid.

His Honour said that the plaintiff should have obtained orders direct for the extras from the defendant, and that there could be no implied authority. He directed a non-suit to be entered. This was said to be a test action.

THREATENING A BUILDER.

At Westminster Police-court, John Davis, 64, labourer, of 31, Romney-street, Westminster, was charged before Mr. Partridge with demanding money with menaces from Mr. David Walker, at Johnson-street, Westminster.

Mr. Walker, manager to the prosecutors, Messrs. M'Lachlan & Sons, builders, of Johnson-street, Westminster, said that morning the prisoner, who was a stranger to him, came to the office and asked to see one of the firm. He gave no name, and on being asked what his business was, he said he wanted to see Mr. M'Lachlan about the concrete work at the British Museum. It was not "put in" as specified, and unless it was made worth his while it would have to be taken out again. The prisoner also said that it would cost the firm 50*l.* to take it up and alter it. The witness asked him who he was, and whether he had been working on the job. The prisoner said he had not, he was a Government inspector, and had access to the place, and had been there eight or nine times. The witness asked him what he expected, and the prisoner said, "I will leave that to you; give me something and you shall hear no more about it." In reply to a question from the witness as to what Governmental department he represented, the prisoner said he came from Woolwich. In reply to the magistrate the witness said the firm were building a new gallery at the British Museum, and great part of the site was concreted.

The prisoner denied that he made any demand for money. Instead of the builders using concrete at the Museum, they had used old brick rubbish, and covered it over with a thin layer of concrete. The contract stated that they should put in a layer of 7 ft. of good concrete, but in some places they had not covered the old bricks and rubbish with more than 4 in. It was a disgraceful piece of work, and ought to be looked into.

Mr. Partridge remanded the prisoner, consenting to accept bail,—one surety in 20*l.*

CONDITION OF FAREHAM.

A correspondent to be relied on, signing himself "Quæstor," makes some serious statements as regards the sanitary condition of Fareham,—statements that show the necessity for immediate interference on the part of the Board of Health. The sewage is poured into the upper part of Portsmouth Harbour; the sewers are partly choked, so that in the principal street when there is heavy rain the contents of the sewers find their way back into the cellars of the houses; the burial-ground is full, and the water supply contaminated. This is brought about, he says, by the pernicious system of supplying closets direct from the water main. "All the water-closets of the small houses, and all the servants' closets of the large houses, with few exceptions, are supplied from the ordinary house supply, without an intermediate tank. Anything more disgusting as well as dangerous cannot well be conceived. When the water is stopped, as it is every night and once or more in the day time, the water receding in the pipes supplying closets sucks in the foul air direct from the closet-pans, and any water remaining in the main or subsidiary pipes is impregnated by this poisonous element, and the poisoned liquid is the first supplied to the houses when the water is again turned on at the waterworks. Any person drinking, say, half a pint of this deadly mixture, which he might readily do if he happened to draw for that purpose the first water in his house when it was turned on afresh, would certainly be very ill, if he did not die outright. Should there be an epidemic in the town, such as cholera or typhus fever, the germs of those fatal diseases would be spread through the town with fearful rapidity from the source mentioned, and from the causes dealt with in this letter nothing can be more probable than an epidemic."

The Local Government Board ought to be applied to if the Fareham Board do not move immediately.

MODERN STONE-CARVERS.

Sir,—At Kansas City, in Western America, more thousands of miles from my pleasant home at Exeter than I am prepared, at the present moment, to quote off-hand, I have just received a pile of *Builders*, and have, amongst other matter, been much interested in the perusal of a paper in one of them upon "Monuments" (the *Builder*, June 11, 1881, p. 741). Exception, however, I think, must be taken to the statement therein that "many of the best stone-carvers at work here" (in London) "are Italians, and the most expert amongst the English ones have studied in Italy"; and again, further,—"At present the phenomenon of the employment of foreign stone-carvers to execute works comparatively simple may, perhaps, point to some deficiencies in our art and technical schools."

The writer of the above is assuredly in error. The best stone-carvers in London are *not* Italians,—they have not studied in Italy, and when comparatively simple works are executed in London, foreign stone-carvers are not employed to do them. Messrs. Farmer & Brindley, Thomas Earp, James Forsyth, and numbers of other good men in London, are daily doing the best possible work, and those in their employ are, as a rule, honest Britons, not one out of hundred of whom were ever nearer to Italy than Saffron-hill! An ordinary percentage of foreigners exists amongst carvers, just as they do amongst all other trades, but the assertion that the highest class or any class of stone-carving in London is in the hands of Italians, cannot be too emphatically denied.

I have always been a rolling stone, and at the present time I find myself, as a relief from business, taking a holiday through the United States. Twenty years or so ago, at this time, I remember I was in Italy earning a miserable pittance there as a carver,—for wages were dreadfully low at the time. I recollect the jealousy of my fellow-workers, and that oftentimes a beetle-browed Italian would scowl darkly, and taunting me with "taking the bread out of his children's mouths," would go through the pantomime of stabbing me. I used to laugh,—for an Englishman's fist is better than an Italian's knife any day of the week. But the incident goes to show what different treatment is received by the Englishman in such countries as Italy and Spain to that he generously bestows upon those he receives in hospitable England.

During the time I was at work in Italy, and I went from one end of it to the other, I saw nothing to suggest that the modern Italians, as a race of workmen, were ahead of, or even level with, the English. The present generation in that sunny land, indeed, pride themselves rather upon the remembrance of past greatness than upon the possession of present skill.

Let any reader go to the first good job he may know of in London where stone-carvers are at work, let him question the artists themselves, and I will guarantee that he will not find more than one Italian in every twenty men.

Harry Hems.

UNFAIR COMPETITION.

Sir,—As one who tried for the surveyorship to a Yorkshire drainage commission, I received a reply that "an appointment had been made fo a gentleman who has long been officially connected with this drainage." Now, if competent, he, of course, is the proper person for them to appoint, and so far I am content to be an unsuccessful candidate; but does it not seem the height of injustice to put a large number of persons to the trouble and annoyance of getting together their testimonials and going through the empty form of an open competition, when, in point of fact, the Board had a suitable man at hand, and whom they, no doubt, always intended to select? The greatest annoyance to me is that I feel I have been "made a fool of"; but to some it is more serious, as, unfortunately, asking for a testimonial often disturbs the good feeling existing between employer and *employé*, creating an idea of discontent with his present lot, on the part of the younger man, which is often most unjust and injurious to his interest; and in the interest of all who are seeking to improve their professional position I must strongly protest against public bodies advertising for surveyors, &c., when they have already made an appointment among themselves. The advertisement in this case was, very strangely, not in your valuable journal, nor in any professional paper, but in local papers, and the qualifications were merely to survey, level, plot sections, and take the management of men, so that it did not appear at all necessrry to have been connected with drainage previously. Fair Play.

DAMAGE TO THE LANTERN OF WIMBORNE MINSTER, DORSET.

Sir,—All lovers of architecture and antiquity will be sorry to hear that another act of Vandalism has been committed at this church. The unique external Norman arcading, built of a local brown sandstone, is being repaired in white stone, destroying the whole beauty of the tower.

I am at a loss to account for the use of Bath stone. As a proof that this brown stone can still be obtained, and is used for building purposes, I may mention that Mr. G. E. Street used it in the building of St. Peter's, Bournemouth, and the church at Spokesdown.

Mills Robbins,
Hon. Sec. of the Bournemouth Field Club.

THE MELBOURNE AWARDS.

Sir,—It may support your own observations, and interest and instruct some of your readers, who, like myself, took honours at Sydney in the Art Section and failed to do so at Melbourne, if I ask you to publish the extract I append from a letter written to me by a highly-intelligent settler in Victoria, who takes great interest in art, and has done honour to the old country.

Architect.

"I did visit our Melbourne Exhibition, and but for the catalogue I should never find your contribution. It is situated on the staircase leading to picture galleries, among a group of architects' works; even with the catalogue I should not be able to find it had I not the help of an opera-glass. The staircase is not over well lighted, and this is high up. The *Australian* says that these works had to be put where they are for want of room. If the judges succeed in seeing its merits they must be very painstaking, and have splendid eyesight or good opera-glasses."—*November 27th*, 1880.

DAMP: A QUESTION.

Sir,—I have only to-day noticed a letter with this heading in your paper of the 30th ult. I think the solution is simple. The cellars should not be deeper than the drain-pipe. The water collects in the clay around and under the house, and in the dry weather the atmosphere draws the water out of the ground to the surface. In the wet weather the pressure of the atmosphere has a contrary effect. The occurrence is too frequent to warrant the term "phenomenon." An experienced man should have no difficulty in rectifying this trouble, but it would certainly entail some expense. J. Eberhard.

THE LANCASHIRE AND YORKSHIRE RAILWAY STATION COMPETITION.

Sir,—May I be allowed to call your careful attention to the very recent Lancashire and Yorkshire Railway Company's New Station competition, and the awards?

I have not time this week to forward you a truthful *exposé* of the whole transaction, but I promise to do so next week, when I think I shall be able to show in detail how unjustifiably the premiums have been awarded, and what (as I think) a gross injustice has been done to many very able men who sent in designs.

A Non-Competitor.

Miscellanea.

Friendly Meetings.—A desire for social intercourse on the part of members of the Council of the Royal Institute of British Architects has been prevailing, and with agreeable, not to say useful, effects. Mr. David Brandon, F.S.A., had sought to entertain at dinner on Monday last all the members of the Council, including the country members, but was disappointed to a certain extent in consequence of their absence from home, mainly in search of health and recreation abroad or in the provinces. A pleasant party, nevertheless, responded to his invitation at the Conservative Club, in St. James's-street, including the president, Mr. G. E. Street, R.A., Mr. Barry, Mr. Currey, Mr. Christian, Mr. G. Godwin, Mr. Hansard, Mr. l'Anson, Mr. Wm. H. White, with Mr. G. G. Adams, Dr. Christie, and other private friends, and an agreeable evening was, naturally enough, spent.

The Electric Light at King's-cross Station.—The King's-cross Station of the Great Northern Railway is now lighted by means of electricity, a beginning having been made last week. The peculiarity of the Crompton system (which was described by us some time ago) is that arc lights of large size are used, which are produced by self-regulating lamps, three or four being placed upon the same circuit. There are twelve Crompton lamps within the station, six being placed over the arrival platform, and a similar number over the departure platform. Two other lamps of larger size are placed outside the station building. The interior area lighted consists of two bays, each 880 ft. long and 105 ft. wide, and 72 ft. high, as well as the cab rank adjoining the arrival platform, which is 40 ft. wide. The total area lighted is 220,000 square feet, giving an area of 18,333 square feet, or nearly half an acre, to each lamp. The lamps are suspended at a height of 30 ft. from the platform level, and are arranged on four circuits, the light of each lamp being computed as equivalent to 4,000 candles. The illumination of the platform area is both uniform and excellent. The two exterior lights are estimated at 6,000 candles each, and are placed at an altitude of 70 ft., the lanterns being of clear glass. The current is supplied by means of five Burgin dynamo-electric machines, which are driven by a 12-horse-power semi-portable engine by Messrs. Marshall & Sons, of Gainsborough, working up to 35-horse-power, and having been designed and constructed specially for its present work. The shed in which the engine and machines are placed is about 250 yards from the nearest point of the station, and is lighted by the Swan electric light.

Decoration in the House of Commons.—Mr. Schreiber on Tuesday called attention to the unfinished state of the Central Hall of the Houses of Parliament, and submitted a resolution declaring that the decoration of the central hall, interrupted twelve years since, should now be resumed and completed in mosaics. The hon. member argued that public money would be well spent in decorations tending to promote the enjoyment of the people by appealing to their higher tastes. Mr. C. Bentinck argued that the taste of the present day was bad, and that all mosaics executed in recent times were failures, while he laid down the proposition that public money should only be expended as to matters of this kind in the purchase of well-known and well-established works of art, or else in the encouragement of British manufactures and British art, and generally of British interests. Mr. Shaw Lefevre admitted that it was desirable to complete the decorations of the central hall in a style worthy of its architectural beauty, but deprecated haste to fill up the empty panels without certainty that the works of art to be inserted came up to the highest standard. The fact that the subject had been in abeyance eleven years proved that the question was not one of urgency; and there was no such general assent upon the subject as made it desirable to ask for a vote to complete the decorations now.

Christmas Cards Competition, Suffolk-Street.—The prizes have been awarded, and a large number have again been obtained by the ladies. The first prize, 200*l.*, has been gained by Miss Alice Havers ("A Dream of Patience"); the second, 150*l.*, by Mr. E. K. Johnson ("Single Figures, Winter Scenes"). Messrs. Hildesheimer & Faulkner, the originators of the competition, have purchased a large number of the designs contributed, beyond those to which the premiums have been awarded according to the published particulars. Considering that the awards were made by Messrs. Millais, Marcus Stone, and G. A. Storey, after the designs were hung, it says something for the cleverness of those who hung them when we mention, that all the premiated designs are in the large room, and that these, with very few exceptions, are on the eye line.

Christchurch.—The Restoration Committee of the Priory Church, Christchurch, Hants, have appointed as their architect Mr. B. Edmund Ferrey, who recently examined and reported on the body of the building. The roof to the north transept will be the first portion of the work proceeded with, as it has been found to be in a very decayed and almost dangerous condition.

A Large Piece of Glazing.—Carlisle Citadel Station, which is glazed on Rendle's "Patent Indestructible System," has an area of 330,000 square feet. Messrs. Blythe & Cuningham were the engineers.

Nuisance.—The case of Bonner *v.* The Governors of Sutton Hospital was an action of nuisance, heard at the Croydon Assizes the other day before Mr. Justice Field. The plaintiff is a builder at Godalming, and had purchased some land on which he had erected some houses. The defendants, who are the authorities of Charterhouse School, are owners of some adjoining land, on which they had erected gas-works for the purpose of supplying the school building with gas. James Bonner, the plaintiff, stated that in 1869 he purchased the piece of land and built houses on it. One of the Charterhouse masters became tenant of one of them. Gas was first made in September, 1878. After the tenant in question left, the house remained untenanted for twelve months. The smell from the gasworks was very bad. For the defendants it was contended that the nuisance complained of had been greatly exaggerated. Mr. Louis M. Stuart, the tenant of the plaintiff's house, said that he took it first at 30*l.*, and afterwards at an increased rent of 45*l.* On the average, there were sixteen boys boarding in his house. He felt no inconvenience from the proximity of the gasworks. After some time the jury intimated that they had made up their minds that the gasworks were a nuisance, and judgment was given against Dr. Haig Brown, the head-master, the mode of assessing the damages to be settled by the learned judge in case of difference between the counsel on both sides.

Cottage and Window Gardening.—The first flower-show of the Shaftesbury-park Garden Improvement Society, of which Sir Trevor Lawrence, bart., M.P., is president, has been held. The society, which was only started some four months since, has for its object the encouragement of such humble floricultural efforts as may be practicable in the tiny plots of ground dignified by the name of gardens on the Shaftesbury-park estate, near Clapham Junction. The movement was originated and is being carried on by a few of the residents, who are for the most part artizans and mechanics; and, considering the short time they have been at work, the results already attained are described as very gratifying. Prizes were offered for the most attractive gardens, the best arranged windows, the best specimens of climbing plants on walls, as well as for plants in pots and out flowers. The schedule was carefully arranged, there being separate classes for gardens and windows with warm or cold aspects. A large number of competitors entered for all classes. Sir Trevor Lawrence visited the show in the afternoon and addressed those present, and in the evening Mr. J. Somervell, chairman of the committee, distributed the prizes, which consisted of books and articles, useful and ornamental; and a vote of thanks to the committee and secretary (Mr. B. Wynne) wound up the day.

Auckland New Cemetery: Tenders Accepted.—A meeting of the Burial Board for Auckland district was held recently, presided over by the Vicar, Canon Long. The architect for the new cemetery, Mr. Pritchett, of Darlington, reported that he had made inquiries respecting the contractors whose tenders were provisionally accepted at the last meeting, and the result was satisfactory. The tenders were then formally accepted as follows:—Mr. Carrick, of Durham, for road-making, draining, and laying-out; Mr. Ridley, of Tow Law, for mason's and plasterer's work; Messrs. Blackett & Beetham, for carpenter and joiner's work; Mr. Pollard, Bishop Auckland, for slater's work; Mr. Wouldhave, Bishop Auckland, for plumber and glazier's work; Mr. Willis, Darlington, for painter's work. The cost of the work is,—for fencing and gates, about 500*l.*; for roads, drains, laying-out, and planting, about 600*l.*; chapels, tower, and spire, about 1,450*l.*; superintendent's house, about 450*l.*; total, a few pounds under 3,000*l.*

Royal Polytechnic Institution.—Mr. Wm. Stokes is introducing some valuable new suggestions in his lectures here upon the improvement of the memory, and is explaining the practical application of his system for teaching the multiplication table by means of easily-remembered pictures.

Buildings for Dover.—It is proposed to erect a block of municipal buildings on the site of the old borough prison. The work, when completed, it is estimated, will involve an expenditure of at least 25,000*l.* Some of the local residents are protesting against the proposal.

Lambeth Palace Library will be closed for six weeks for the recess from August 29th.

The Chew Magna School Board have appointed Mr. E. Henry Edwards, of Bristol, architect for their new schools.

TENDERS

For new contagious wards, infirmary, &c., Doncaster Workhouse. Messrs. Wilson & Masters, architects. Quantities by the architects:—

J. Chambers & Son, Sheffield	£6,790	0	0
W. Anelay, Doncaster	6,290	0	0
Houldsworth, Bradford	6,165	0	0
Beastall, Doncaster	6,237	0	0
Illingworth, Bradford	6,150	0	0
Fidler, Chesterfield	6,056	0	0
Chadwick, Rotherham	5,898	0	0
Tomlinson, Leeds	5,767	0	0
Humphries & Moulson, Bradford	5,568	0	0
Arnold, Doncaster	5,544	0	0
Atkinson, Gateshead	5,535	0	0
Dennison, York	5,479	0	0
W. Smith, Sheffield	5,465	0	0
Nicholson & Son, Leeds	5,161	0	0
E. Meggitt, Thorne	5,119	0	0
Wortley, Kilnhurst (accepted)	5,100	0	0
Earnshaws, Rotherham	5,090	0	0

For the erection of boundary walling, Rutland Park estate, Sheffield. Messrs. Wilson & Masters, architects:—
J. Stone, Sheffield (accepted)

For the erection of eight houses, Nether Hall-road, Doncaster, for Mr. J. Brailsford. Messrs. Wilson & Masters, architects:—
Barker, Doncaster (accepted).

For the Doncaster Cemetery Extension, for the Cemetery Commissioners. Messrs. Wilson & Masters, architects. Quantities by the architects:—

Masonry, &c.

Stanley, Doncaster	£887	14	0
Athron Bros. & Gill, Doncaster	842	14	0
Barker, Doncaster (accepted)	703	11	9
Farnival, Doncaster	650	0	0

Ironfounder's Work.

Micklethwaite	372	0	0
Newton, Chambers, & Co.	312	0	0
Ratcliffe	297	0	0
Yates Haywood	282	0	0
Hatteraley & Co.	227	0	0
Whiteley	220	0	0
Crossley (accepted)	204	5	6

For taking out window-heads and iron columns, and building new stone piers at the Town-hall, Welshpool, for the Corporation of the borough. Mr. R. Hurst, architect:—

J. Potter, Welshpool	£205	0	0
J. W. Roberts, Welshpool (accepted)	190	0	0

For painting and decorating the assembly and tea rooms at the Town-hall, Welshpool, for the Corporation of the borough. Mr. R. Hurst, architect:—

E. Preater, Newtown	£140	0	0
J. Forse, Shrewsbury	93	3	0
J. & A. Smith, Welshpool	69	10	0
C. Lewis, Welshpool (accepted)	55	18	9

For building a dwelling-house at Welshpool for Mr. W. T. Parker, J.P. Mr. R. Hurst, architect:—

C. T. Pugh, Welshpool	£220	0	0
D. P. Jones, Welshpool (accepted)	202	10	0

For rebuilding the Three Tuns, Welshpool, for Mr John Roberts. Mr. R. Hurst, architect:—

J. Potter, Welshpool (accepted)	£493	0	0
D. P. Jones, Welshpool	487	0	0

For whitewashing and varnishing to inside, and varnishing to outside, at Board of Works Offices, Greenwich:—

Stevens	£130	0	0
Castle	103	0	0
Bailey	95	10	0
Hatfield	92	10	0
Lyon	85	0	0
Gillard	78	0	0
Pierce	71	10	0
Holding	68	0	0
Chapman	65	0	0
Davis	64	10	0
Gale	49	12	0
Challis (accepted)	45	0	0

For a new front and internal alterations to No. 84, Peascod-street, Windsor. Mr. T. V. H. Davison, architect:—

W. Bond	£378	0	0
W. P. Reavell	351	0	0
F. Akery	324	0	0
J. Willis	318	0	0
R. Bishop (accepted)	308	0	0

For the erection of a new Baptist Chapel, Adelaide-square, Windsor. Mr. T. V. H. Davison, architect:—
E. Knapp (accepted).

For new mahogany fittings for Mr. F. Gorringe's new premises, Buckingham Palace-road. Mr. J. T. Walford, architect. Quantities supplied:—

Trebel & Son	£2,570	0	0
Drew & Cadman	2,240	0	0
F. Sage (accepted)	1,950	0	0

For the erection of a house in Lewin-road, Streatham, for Mr. James Amsden. Mr. W. Paice, architect. Quantities supplied.

R. & E. Smith	£1,100	0	0
Sawyer	1,093	0	0
Downs	980	0	0
Young, Cochrane, & Frazer	893	0	0
J. O. Richardson	890	0	0
Smith	884	19	4
Thorner & Co.	876	0	0

For the erection of lodge to Intercepting Hospital, Queenstown, for the Cork Board of Guardians. Mr. D. J. Coakley, architect:—

Burke	£103	0	0
Flynn (accepted)	92	0	0

For the erection of [a villa residence at Ashford, for the Directors of the House Improvement and Supply Association, Limited. Mr. A. Bedborough, architect. Quantities supplied by Messrs. R. L. Curtis & Sons:—

Balaam, Bros.	£3,155	0	0
Howell & Son	2,620	0	0
Hobern & Co.	2,600	0	0
D. C. Jones & Co.	2,444	0	0
Naylar & Son	2,398	0	0
E. Vaughan	2,377	0	0
R. Avard	2,349	0	0
G. Parker	2,343	0	0
Wallis & Clements	2,274	0	0

For rebuilding the Grosvenor Arms, Grosvenor-street, Bond-street. Mr. W. Seth Payne, architect. Quantities by Messrs. Hoveden, Heath, & Berridge:—

G. H. & A. Bywaters	£2,760	0	0
J. Outhwaite & Son	2,703	0	0
J. H. Tarrant & Son	2,691	0	0
Robt. Perkins	2,647	0	0
E. Conder	2,600	0	0
Lathey Bros.	2,595	0	0
E. Lawrence	2,580	0	0
Richard Conder	2,535	0	0
W. Scrivener & Co., 8, Euroya-road, Regent's Park (accepted)	2,494	0	0

For alterations and decorations to No. 9, Upper Bedford-place, Russell-square. Mr. W. Seth Payne, architect:—
Broad & Son, 61, Kenton-street, Russell-square (accepted) £225 0 0

Homer as an Architect: The Palace of Ulysses at Ithaca.

HE agreeable occasion for the present article is the reception of a *brochure* from our friend, M. Charles Lucas, of Paris, an honorary member and correspondent of the Royal Institute of British Architects. The subject is "Architecture in the Time of Homer, especially as illustrated by the Poet's Description of the Palace of Ulysses," and is extracted from the "Annales de la Société Centrale des Architectes." M. Lucas adverts to the study of the subject having occupied and consoled the leisure which for years was enforced upon French architects by the consequences of a great political reverse; but the study bore its fruit under pleasant circumstances when the results were brought before the profession at a congress of French architects, and in the hour intermediate between a distribution of rewards and a "confraternal" dinner. The style of the author has all the gracefulness to which the French language seems to lend itself as naturally as to lucidity of exposition, and exemplifies the amenities not only of professional but of international intercourse. M. Lucas refers to articles of the *Builder* on the same subject, June, 1870 (quoted and translated pp. 14, 37, 39, 41, 48, 51) with a frankness and cordiality which must not be allowed to mislead his readers as to the genuine independence of his own judgment and studies.

In an introductory notice the author gives particulars of a primitive house, excavated, "like a prehistoric Pompeii," in the volcanic island Therasia, in the Greek Archipelago. It was built very rudely of irregular blocks of lava, with mud only for mortar,—such things have been known even in historic times; some rooms had upper stories, but all the beams employed were undressed, retaining even the bark. The cut of the more important,—most important,—gate of Mycenæ from another work has the unsatisfactoriness of so many other representations. We would fain take this opportunity to urge that an accurate cast of this monument should be preserved in every architectural museum that pretends to instruct in the history of our art. The mouldings even of the pillar itself, as well as of the members above and below it, are given so differently in different engravings that some must be miserably falsified, and all uncertain. Not merely the degree of diminution of the shaft from above downwards, but even the fact of any diminution at all is placed in doubt by some drawings. It seems to be much slighter in reality than usually represented, and that in consequence of a peculiar optical illusion which few are aware of. The nature of this will become evident to any one who will hold up before him the drawing of even an Ionic column upside down: he will be surprised at the greater quickness with which the girth of the column will then seem to expand upwards. The same effect, let the natural philosophers and opticians explain it, will be experienced when the Ionic column of a portico is looked at from above,—let us say from the box-seat of a coach. If we may trust the profile given in a number of the *Archäologische Zeitung*, the mouldings of the capital are exactly those of the Attic base reversed; upon the verification of this more historical inferences depend than affect the development of architecture alone. It is time, however, to return to our proper subject. M. Lucas engraves three schemes for a restored plan of the palace of Ulysses. One is by Canina; another by Lechevalier, who, in 1829, writing under the pseudonymn of Constantine Koliades, revived an ancient paradox of the identity of the poet and his hero,—a Homer-Ulysses. Both these work upon the indications, reported by Sir Wm. Gell, of ruins upon Mount Aito, in Ithaca. M. Lucas justly styles these indications both scanty and questionable, and valueless as a check upon the descriptions by Homer. In fact, it cannot be too distinctly recognised that the poet gives such very inaccurate bearings for the island of Ithaca itself, that he could neither have been familiar with it personally nor have owed his information to others who were so. This state of the case will be found fully established in Bunbury's recent "History of Ancient Geography," a thoroughly standard work, if the Victorian era has one to boast of. The third plan, which has the advantage, at least, of being unhampered by restricting local conditions, is by H. Rumpf, and illustrated a Latin Essay, which we have not seen, published at Giessen in 1858.

What has to be treated of is, in fact, the conception of the poet. This, doubtless, may have been quite at variance with the real architecture of the remote epoch professedly dealt with, and also with the art as contemporary with the poet; but to this latter it must necessarily have been indebted for suggestions more or less extensive, as it must have been, in some degree, to his familiarity with traditions and monuments which, in his ancient days, survived from days that were still more ancient. In any case we are quite justified in expecting that his ideal conception will prove to have been both self-consistent and complete. It is a frequent experience of analysts of superior works of fiction, to come upon casual indications that an author had realised in his mind a scheme of local details or personal relations more minutely and scrupulously made out than he ever had occasion to define for the guidance of his readers. M. Lucas, unfortunately, does not supply an engraved plan to illustrate his own exposition; pursued, however, as it is, with excellent consistency and careful references and citations of the poem, it invites recurrence to the subject, and a summary of general results. It is to do honour to the candour of a *confrère* from beyond that Channel which now is a high road of happy intercourse between nations which it was long chiefly valued for dividing, that we reproduce his note of cordial acknowledgment (p. 37):—"C'est surtout dans cette troisième partie de notre travail (Le Palais d'Ulysse) que nous avons pris pour guide la savante étude parue dans le journal Anglais, *The Builder*; et nous sommes heureux de reconnaître que dans certains passages, nous n'avons fait que traduire et reprendre, avec l'archéologue Anglais, auteur de cette étude, le texte de l'Odyssée," &c.

If Homer assigns to Ulysses a palace in many respects of primitive simplicity, and even rudeness, it was not by any means because imagination was wanting,—or, it may be, familiar models either,—for furnishing his hero with a superb and luxurious dwelling. His descriptions of the palaces of Alcinous and Menelaus might have satisfied the author of "Lothair" for unsparing magnificence, and the employment of metals in their solid architectural enrichments is such as the so-called Treasury of Atreus at Mycenæ proves to have been suggested by executed works.

The ancients amused themselves by ungallantly reckoning up the age of the wife for whose sake Ulysses was fain to desert the society of goddesses. Ovid, from the depths of his cruel exile, though he felt its cruelty severely in the rupture of his own affectionate domestic relations, could murmur that the much-enduring man had, after all, no such hard lot in his separation,—*An grave sex annos teneram fovisse Calypso?* But the strong home-feeling of Ulysses is the great redeeming charm of a character which does not otherwise shine by the amiable virtues; and this is set forth in most engaging relief by his yearning for a homestead so contrasted with splendours and luxuries which he can despise for the sake of it, keen as is his eagerness for wealth in any form, and indifferent as he usually is as to how he comes by it. There is no sea-risk that he is not willing to incur, no perils afterwards that he cares to shun, if only he may see once again the smoke ascending from his native roof.

Let us call again to mind the general character and scheme of this dwelling so ardently longed for, as they come before us vividly in the revisal of M. Charles Lucas.

The home of Ulysses was a combination of palace, manor-house, and farm-house, in relation to which the homestead to which his aged father has retired is very much that of the home farm. His wealth, apart from a store of precious and useful metals and arms,—plunder obtained in war and athletic prizes,—consists very largely in stock,—beeves, swine, and goats; and with these we must include slaves of both sexes, captured or purchased. The account which Eumæus, the faithful swineherd, gives of his master's stock, both on the island and the main-

land, is extraordinary; we may safely say extravagant, for allowance has to be made for an old servant's unscrupulous concern for the dignity of the family. We are only brought into communication with swineherds, goatherd, and herdsmen; but there is clear reference to a number of men that might have mustered, if time allowed, from those engaged in cultivating the large royal demesne.

Outside and in near connexion with the palace was a prepared and levelled platform adapted for athletic but also sedentary games, and a general lounging-place: this was an arrangement which, treated architecturally, became either the Hellenic Palæstra or else a *lesche;* but it is clear from Homer's allusion to the beauty of the chorus or dancing place which Hephæstus constructed for Ariadne at Cnossus, that he was already familiar with application to such sites of study and embellishment at establishments more luxurious than that of the Ithacan prince.

The entire palace is contained within an outside wall, crowned with a coping where it is single, and of such strength and height as to secure inmates and contents from intrusion and violence. The main, and apparently the single, entrance into the enclosure, was through doors capable of being thoroughly secured, and wide enough to admit cattle and chariots; on the same front, exterior to the general wall, was some sort of porch or portico.

This entrance admitted to the *aule*,—a spacious courtyard, where the cattle brought for slaughter could be tied up or turned loose for a time; stalls and stables, when such were required, had their position here, but consistently with the ruggedness ascribed by Telemachus to the surface of his native island, there is no mention of the use of horses in Ithaca. This seems to have been the position of the outhouses, where the female servants were employed laboriously at the hand-mills to provide a supply of flour for the household. The droppings of the cattle removed from the *aule* were heaped outside the building, but not very far away, to await distribution over the estate. Lying neglected and weak upon the dunghill here, close to the gates, was the dog Argus, as Ulysses approached his home after twenty years' absence; the creature recognises him, disguised as he is, and, indeed, transformed in personal appearance by the goddess Athene.

"He knew his master,—knew and strove to meet,—
In vain he strove to crawl and kiss his feet;
Yet, all he could, his tail, his ears, his eyes,
Salute his master. . . . . .
The dog whom fate had granted to behold
His lord when twenty tedious years had roll'd,
Takes a last look, and, having seen him, dies,
So closed for ever faithful Argus' eyes!"

In the centre of the *aule* was an altar dedicated to Zeus as guardian of an enclosure. Unfortunately, no hint occurs to determine a special orientation for the building, which might explain an epithet, implying warmth, given to a corridor or open lean-to, which seems to have formed a covered way along one if not both sides of the *aule* from the main building to the outer doors. This *aithousa*, in any case, had greater importance on the side opposite the outer doors, and on each side of that which admitted into the dwelling proper.

This second entrance on the main axis of the building is identified by references to its threshold as of wood, in contrast to another, which is of stone or marble, in the further interior. Passing through it, the first *megaron*, or large apartment, was reached,—a spacious hall, and the ordinary haunt of the men, at meal-times especially, and otherwise. It was of an extent to accommodate very considerable numbers,—accepting the descriptions submissively, we may say some scores. On the occasion of a meal, seats and separate movable tables were arranged along the opposite sides of this for the guests; a fire could be lighted in it, of which the smoke escaped through an opening among the blackened rafters of the roof. How this roof was constructed does not appear; no occasion occurs for the mention of any pillars; one support is alluded to, by which Penelope takes her stand, in a manner that almost implies that it was as single as the central shaft of a chapter-house, but this is at the further end of the apartment. It does not even appear that the floor was either boarded or paved; indeed, there are indications that it was at best of beaten earth, capable of having a trench dug in it and to be cleansed by scraping with hoes. We hear nothing of a separate kitchen for the preparation of the flesh which is so freely consumed, with no mention of vegetables, either fresh or cooked; and the newly-flayed hides of the slaughtered beasts are lying about near the seats, where wine is being quaffed out of golden goblets. But it would be very rash to assume that the manners and customs of the poet's own age or a preceding are accurately represented by the picture which it suited his poetical purpose to compose.

This principal hall of the men was central between the *aule* and the more private and the peculiar feminine division of the house beyond. A central doorway, with a stone threshold, admitted to these apartments, of which the principal is again called a *megaron*,—a large work-room in which the numerous female servants were occupied with manipulation of wool, and where Penelope herself occasionally applied to the distaff and spindle. The best bedroom of Ulysses was on the ground-floor in this division, and there were underground storerooms for wine, oil, and meal, of which a discreet female housekeeper had charge. A yard of sufficient extent for a considerable number of poultry to be kept, was also within the enclosing wall, and answered at this extremity of the building to the *aule* at the other. The chamber usually occupied by Penelope is on an upper floor on this side, and in such proximity to the hall of the men that she has no difficulty in overhearing what goes on there; the locked treasury of Ulysses is also on this story. But between the enclosing wall and the lateral walls of both the great apartments, there was arranged, on one side at least, a service-passage of indeterminate breadth, with stairs, to rooms above it. This could be entered from the further end of the *megaron* of the men, and gave an issue into the *aule* near the door with the "wooden threshold." There was also access to it from the women's division, who were thus enabled to pass by the side door into the *megaron* of the men, which they put in order after an entertainment, and also to reach the *aule* and so leave the palace as required without traversing the central hall. They could also pass by it to such upper rooms as the armoury and others, for domestic purposes. Telemachus, for example, is lighted by his old nurse to his chamber, in a position whence he could look down over the courtyard and the entrance.

The general distribution has much agreement with that of the Greek house as described by Vitruvius.

When the seeming beggar, Ulysses, is pitted by the suitors against the beggar Irus in a boxing match, the fight "comes off" in the middle of the *megaron*, and the victor drags the vanquished bully by the leg through the vestibule, across and out of the *aule* and sets him up against the enclosing wall outside. When the crisis of the poem is at hand, and Ulysses is about to set upon the suitors, he provides for shutting off the women's apartments by the indispensable help of the housekeeper, as they have to be secured from within; and the herdsman who is with him is sent to preclude the possibility of interruption from without, by barricading the main entrance into the *aule*. Then he takes his stand with the fatal bow on the wooden threshold to defend the passage from the great hall into the *aule*, and at the same time to command the exit by the service passage which was close by; and then the massacre commences.

So it is that we have had satisfaction in going hand-in-hand with M. Charles Lucas in verification for the most part, of the results which he obtains by following the incidents of the Odyssey in order, and combining scattered allusions, epithets, and phrases. Like a genuine student, he does not withhold from inviting excursions along the margin of his main subject into collateral topics of illustration more or less immediate; these invitations are ever rife in classical antiquity, for the genius of the Greek asserted its originality in every art, and the same spirit which animated the literature was evidenced harmoniously both in architecture and in graphic design. In obedience to this impulse we are welcomely presented with a reproduction of the subject on an antique mirror representing an interview of Ulysses and Penelope. This is reproduced from the publication of the German Archæological Institute of Rome, but with the title there assigned and summary of explanation which miss the intention of the ancient artist. It is called "Ulysses relating his Adventures to Penelope," and as the dog Argus is introduced, which, according to the Odyssey, dies before this meeting, it was assumed that the artist followed one of the many lost cyclic poems. But this is to employ a random supposition with the effect of defrauding the designer of the mirror of the credit of an original poetical combination of considerable merit. He clearly had in his mind the incident in the Odyssey when the disguised Ulysses, his fictitious narrative of adventures already concluded, assures Penelope that her husband will return forthwith, while she, on her part, expresses all but absolutely her failure of hope. Ulysses wears the conical sea-cap which he appears in on a coin of Ithaca that M. Charles Lucas engraves, and that Flaxman has made familiar to us. Various disproportions apart, his attitude and gesture, as with fixed gaze he rests his right elbow firmly on his raised left thigh, and extends his index finger in a line with his profile, are admirably invented as expressive of firm conviction and positive assurance. Penelope stands opposite, erect, with folded arms, and one hand to her chin, wrapt in thought, absolutely reserved, if not absolutely incredulous. A Medusa head with a crescent, between the two figures, is a manifest symbol of the monthly term within which Ulysses limits the fulfilment of his assurance:—

"When the pale empress of yon starry train,
In the next month renews her faded wane,
Ulysses shall assert his rightful reign.
What thanks! what boon! replied the Queen, are due,
When time shall prove the storied blessing true?
My lord's return should fate no more retard,
Envy shall sicken at thy vast reward;
But my prophetic tears, alas! presage
The wounds of Destiny's relentless rage,
I long must weep nor will Ulysses come."

The artist of the mirror happily contrives to bring into one scene a contrast which the poet trusts to us to appreciate as presented in successive incidents. He introduces the dog Argus still alive, between the disguised husband and unconscious wife; if, indeed, unconscious, for the ancients disputed whether Homer did not intend us to surmise that the discreet Penelope suspected, or even was confident of more than she avowed or signified. While Penelope is standing almost statue-like, in true suspense or obstinately reticent, the dog, with infallible instinct, with ears declined and curving tail, looks up eagerly to his master, and even strives to attract his attention, fawning upon him with one uplifted paw. The cautious prudence of Penelope could scarcely be brought into better relief,—of the wife who at last, only at last, allows her hopes to become entire and affectionate confidence, when Ulysses intimates his knowledge of their private token. This was the absolute immovability of their bedstead. When Ulysses erected his palace himself, with the skill which he boasts of in all the useful arts of peace as well as of war, he roofed in his nuptial chamber about an olive tree which was growing on the site, and then, on felling it, had left the stump and framed into this the concealed woodwork of his couch, a secret known only to himself and wife and one confidential attendant.

It is difficult to return to the poetry of Homer at any time without lingering over it, and if this is ever excusable it is under the sympathetic circumstances which have prompted the present article.

PATTERN-BOOKS.

The production of books which are intended to supply patterns of work or of design for the use of those who cannot produce their own designs seems to be a type of industry that is much on the increase. Under the general term "pattern-books," which we admit we are here using in a sense of our own, we include all those publications which present collections of designs which have not been executed, but which are published ostensibly for people to "crib" from. Very often the real and primary motive of publication is to furnish a kind of genteel form of advertisement of their author, but the professed end, at all events, is that which we have indicated.

How far such publications are really of value depends partly on the class of object with which they deal. When they are designed to illustrate what is purely artistic work, it appears to our judgment that such books are entirely useless, and even injurious, except in the purely business light of making known their author's name. In any other respect the only result of their use, if they are used, is to encourage the habit of repeating borrowed designs without thought or study. The artisan who uses such a book is merely mechanically copying designs which, even if good in themselves, are not designed for the situation on which he uses them, and the

use of which can hardly be said in any way to stimulate his own taste or knowledge. It is merely parrot work.

The production of works of this kind is, in fact, an indication of a radically wrong notion as to the production of ornamental design. It assumes that certain forms are in themselves art, that they can accordingly be reproduced as art. This, of course, is absurd. Artistic design consists in the exercise of individual thought and taste in the application of well-chosen forms to decorative effect. But to publish the results of such thought for others to use over again is simply to vulgarise them. The idea that decoration can be of any value when borrowed second hand out of a book in this way, is no more reasonable than to suppose that a man can be a good orator by borrowing from a book of selections from another man's speeches.

We do not, therefore, regard such publications with any particular favour, though we may distinguish between the relative qualities of one and another. The last contribution to the list comes to us from Birmingham,* in the shape of a work in four parts (two only are before us) bearing the fashionable title of "Motifs for Decoration," and consisting of plates of designs mostly founded on Japanese taste, or, in some cases, what we might call Japanese crossed with Gothic. The author's preface is amusingly unsophisticated. He says that, knowing practically the requirements and taste of the present period, he has adopted what appears to be the best method of drawing, in the various popular styles, so that, "with comparatively small artistic knowledge, the designs may be adapted to all processes." We had not read this sentence when we wrote the above introductory remarks; it certainly forms a singularly appropriate comment on them. Here is the absolute suggestion, in its naked form, that the decorations given are to supply the place of artistic knowledge, and to be reproduced in any material; quite ignoring the intimate connexion between decorative style and material. The author assumes in the first paragraph of his preface what is certainly not in accordance with facts. He says his aim has been to give a series of suggestions that will readily lend themselves to the various processes of art manufacture; that he has frequeatly felt the want of such suggestions; many of his friends have experienced the same deficiency. Why, there is actually a glut of "suggestions" for ornament of the very highest order in the ornamental work of the past collected in our museums, as well as in such great leading illustrative works as those of Owen Jones and others. Why did not the author publish accurate illustrations of existing ornamental work, and so do a real service to students by disseminating drawings of good work, of historical value, for the benefit of those who were out of the reach of museums? He would then have brought his readers into connexion with typical examples first hand. As it is, a large proportion of his examples are simply Japanese art at second-hand. If they had been careful copies of actual specimens of Japanese work they would have had a distinct and definite value, though a value which it is quite possible to overrate.

As to the actual merit of the illustrations, they are in a good and tolerably bold style of drawing, and in some cases are very effective. The circular panel with the bird (Plate IX.), for instance, is a good bold bit of drawing and design. But then this, and others that are also effective, are nothing but sham Japanese work. The author seems in some cases to have adopted the heresy which Japanese art has (whether logically or not) suggested to many designers in this country, of thinking that it is a good element in design to make everything look as accidental as possible. For instance, in Plate VI. there is a long strip of panel up the centre, with a small diaper on it and circular pateræ of different design placed on the diaper; the said pateræ all at irregular intervals, and all placed so that some part of the disc, less or more, is cut off by the border of the panel. To call this sort of thing "design" is utterly absurd; it is the ignoring of design. "Design" implies contrivance and adaptation, not the complete ignoring of anything of the kind. Another fault is want of homogeneous style; as in Plate II., where sunflowers are decoratively treated, the flowers are conventional, and the leaves nearly natural. This is a fatal error in design. Whatever degree of conventionalism be adopted, it should be carried consistently throughout every detail.

There is another kind of pattern-book which is more useful,—that which combines constructive detail with design. To publish illustrations of the method of constructing and putting together any kind of work, decorative or practical, is always calculated to be useful. Practical knowledge can be imparted by examples; power of design cannot,—not in the same sense, at least. This element in pattern-book making is to some extent illustrated in a portfolio, rather than book, of very awkwardly large sheets, which comes to us from across the water, from Bridgeport, Connecticut, under the title of "Palliser's Useful Details."* This is a joiner's book, and gives a great amount of details of woodwork, designs for gates, railings, &c., accompanied by a good deal of practical detail, such as handrailing diagrams, &c., and nearly everything shown has its section and constructive detail appended. There is nothing to remark on in the constructive portion, which seems to present the ordinary details of joinery, neither better nor worse than are usually followed in the ordinary routine of work; in one or two places there seem to be oversights or omissions, such as the want of throating to a window-sill, unless it is that the drawings, which are rather thickly and roughly printed, do not show it clearly. A good many of the designs, we are told, have been actually carried out, which, of course, actually places the book in a different category from that of mere suggested designs; there is, for example, a plan of the arrangement and constructive details of a shop, which occupies a whole sheet, and there are other such details which may fairly claim to be "useful." Still the object of the work, in the eyes of its producers, is mainly artistic, and in this sense it is rather significant in some ways. In the preface it appears that the aim of the author or authors is very ambitious. They propose to bridge over the gulf between the architect and the inartistic builder and workman by inoculating the latter, so to speak, with the virus of architectural taste. They feel that, owing to the great changes which have taken place in architectural taste "during the last three or four years," the architect and builder have been thrown more apart, and the latter does not at once understand the new ideas of the former, and thus is not only unprepared to carry them out properly, but often is not able to correctly estimate the cost of such new and unaccustomed work, and either estimates too low or too high. Now, when we read this, and we learned also from another paragraph of the preface that it was the special desire of the authors and publishers to keep pace with the times, we turned with some interest to the illustrations to see what was the new taste with which the architects of Connecticut had been endowed. And behold! we find all our old friends of fifteen or twenty years ago in England; the cunningly-chamfered posts, the panels and brackets with patterns pierced in them in round holes and otherwise; the chamfered boarding placed diagonally across the doors, and all the things which characterised average modern Gothic woodwork in this part of the world nearly a quarter of a century ago. Thinking of the phrase "the last three or four years," we turned to the title-page for the date of the book, thinking it was possibly an old work surreptitiously put upon us for a new one; but no, there was the date "1881" plain enough; the only thing that seemed to offer any solution of the puzzle was the date of the month, "First of April." Seriously, however, we presume the conclusion must be that it takes from fifteen to twenty years (allowing for "the last three or four years") for fashions in taste to travel from England to Connecticut, so that about the year 1891, or from thence to 1895, we may expect a book of designs in Queen Anne style from the same place. Far be it from us to assume that our cousins in the States should do nothing in architecture but imitate our fashions, we would rather urge them to avoid mere imitation; but at the same time it seems to be the fact that they do imitate us, and most of the books of designs or buildings that come over to us from the States consist of repetitions of English architectural taste. It is perfectly natural, it is according to the universal course of architectural history in the past, that a race who migrate to a new country should carry with them the architectural traditions of the old country; but then they should leave themselves free to make their own start from these. They should not keep looking back to the old country to note all the changes in fashion there and follow them. In the illustrations we are speaking of there are certainly forms that are new in a sense; but, unfortunately, they are by no means admirable, and are just the kind of things that are produced in the effort to be novel for the sake of novelty, which is always a dangerous experiment.

OBSERVATIONS ON BANKRUPT ARCHITECTS AND THE RIGHTS OF CREDITORS.

It is the lot of every profession for some of its members from time to time to find themselves involved in money difficulties, and architects are not an exception to this general rule. Sometimes an inability to meet in full the demands of creditors may arise from misfortune; sometimes, and more often, from carelessness in the conduct of business. Indeed, the larger does the experience of a man who mixes much among all classes of the community become, the more does it become evident that but few of the so-called pecuniary misfortunes which occur are the results of the inevitable. Want of foresight, a reckless independence of opinion, a desire to make money quickly and not surely, and a want of self-restraint, are the too general causes of pecuniary losses. However, be that as it may, we are now concerned chiefly with facts of a business-like character, and not with the causes of men's misfortunes, and it is in regard to certain facts of considerable importance to architects and their creditors that we now desire to say a word or two. The question, briefly put, to which we wish to direct our readers' attention, is the position of an uncertificated bankrupt architect in relation to his earnings, and this point has been brought somewhat prominently forward of late through the litigation arising out of the construction of a new theatre in the Strand, and especially by the recent case of Emden *v.* Carte, which was tried before Mr. Justice Fry. The exact point arose in this case, and therefore it may be considered as the latest authority which bears on this question, and directly affects the architectural profession. Mr. Emden, an architect, to touch briefly on the facts, brought an action against Mr. Carte in respect of an agreement to employ him as an architect; the main claims were a sum for remuneration for work and damages for a wrongful dismissal, and at the time when the action was begun the architect was still an uncertificated bankrupt. The actual question was raised by an application on the part of the trustee to be substituted as plaintiff in the action in place of the architect.

Now, the legal rule upon this point is shortly this, that the trustee has not a right to the proceeds of a bankrupt's personal and daily labour, for that would be to deprive him of the means of existence. But though this rule is pretty clear on its face, when it comes to be more closely examined it will be seen not to be very easy of application. For what are the proceeds of a bankrupt's personal and daily labour, and what, strictly speaking, is this personal and daily labour? Thus, in one instance, a discussion arose in the courts as to whether a bankrupt or his trustee was entitled to the damages recovered by a newspaper editor for a wrongful dismissal, which certainly was money received in respect of the loss sustained from the breach of a contract in which the elements both of personal and of daily labour were present. In the present instance, the claim of the trustee was also held to be good against that of the bankrupt architect; for, said Mr. Justice Fry, "The conclusion, therefore, at which I arrive is this, that although the personal services of the architect were an inducement to the contract, the fruit of that contract in the way of remuneration or the right to damages for wrongful dismissal would pass to the trustee." And it must be observed that in thus delivering his opinion the judge is careful to insert the words "in the way of remuneration," showing that it was clearly his intention to lay down the rule that whatever an architect might earn by his daily labour in his profession became the property of the creditors as long as he remained an uncertificated bankrupt. Indeed, so far as the creditors are concerned, it would be a hardship if it were otherwise; for the architect's knowledge and professional skill are his capital as much as the actual cash or bills of the merchant, and were it otherwise an architect might become

bankrupt with but small inconvenience to himself. We are not now concerned with other businesses or professions than that of an architect, and, therefore, it is needless to go through the cases which have decided this question in regard to other trades and professions. Of course, a trustee could not perform the contract into which an architect may have entered, but as soon as the remuneration is received then it becomes the property of the creditors. The tendency of the law now is to limit the privileges of a bankrupt as much as possible, and therefore the fruits of personal and daily labour can now seldom escape from the pockets of the creditors, or, more strictly speaking, of the trustee.

SALTBURN-BY-THE-SEA.

One of the best known of the North-Country writers compared the old village of Saltburn to a dove's nest sheltering under the shadow of the ruddy cliffs that rise perpendicularly near it. But this was the ancient village, which had in the distant past a well-deserved reputation for smuggling. That reputation gave place a generation or two ago, as Redcar rose into local prominence as a health resort, to one of another order, for Saltburn became noted for its "fat rascals,"—certain savoury cakes which visitors failed not to appreciate. Slumbering under the shadow of the cliffs the hamlet dwindled, and it is only within the last score of years or so that the situation was appreciated as one of the finest on the north-east coast for a bathing-place. It was one of the directors of the adjacent line of railway who saw the eligibility of the place, and in the course of a few years the crest of the cliff was crowned by a stately hotel, terraces looked from the high ground across the North Sea, a little ravine to the south was turned into pleasure gardens, and rows of modest dwellings sprang rapidly up. Under the impulse of the great trading prosperity that set in in the north-east a decade ago, Saltburn, as the most commanding as well as the youngest of the watering-places of the north, grew rapidly, and bade fair to rival Scarborough. But when the wave of trade depression set in, its reflex action was speedily felt in the health resorts, and it is to that action that Saltburn, owes its unfinished look to-day. Through most of the months of the year it is "remote, unfriended," and "slow," and it is only in the autumn that it wakes up to that semblance of life which society deems good form. In contrast with its busy *bourgeois* neighbour, Redcar, which has a respectable age as a health-resort, and attracts the comfortably-placed shopkeepers for the summer and autumnal outing,—in contrast with Redcar, Saltburn is languid and empty. It does not court the brisk life of the popular health resort, nor the overflowing spirits of the "trippers" who make lively the sands nearer the mouth of the Tees, but to those who appreciate its subdued tone, the pleasures of sea and shore, the scenery of bold bluff and wooded valley, and the deep note of the sea, Saltburn is indeed attractive amongst northern watering-places.

Its site was happily chosen: it is where the sands from the Tees mouth end, ruddy cliffs rising to the south and east, and continuing along a rugged coast broken by little bays and coves at the streams' mouths, to Whitby. Saltburn is placed high, and from it to the north the Durham coast is seen, while far west a veil of smoke defines the course of the Tees. The picturesque coast shows the red face of Huntcliffe Point, that "Huntcliffe Nab" of which Drayton sings as a treasure-house of "stones of a spheric form," which "do headless snakes of stone within their rounds enclose." Between the Point and that part of the town where the Italian front of one of the hotels presents itself, there runs inland from the shore a wide valley, the sloping sides of which are clothed with rich woods, and the grounds of which have been admirably laid out as pleasure-gardens, through which the Skelton "beck" murmurs on its path to the sea. South, the ground slopes upward, and from Boulby, on the coast, to the west of Upleatham, shuts in the moors that intersect the Cleveland district. South and west the great industry of that district shows itself in the puffs of smoke that tell of the mining railways, in the projection of mine-ventilators on the hillsides, and in the rows of mining cottages that here and there dot the green hills and cluster in the valleys of what is a site known in history.

Within a mile or two is that castle of Skelton which was one of the possessions of that great family of Brus that gave kings and queens to Scotland, and dignitaries many to all the three countries. And it has later remembrances, for the predecessor of the present castle was the "Eugenius" of Sterne, and often "Yorick" was the soul of a company "when wit, wine, and mirth" flew round the table. "Crazy Castle" has given place to the structure that now shows its fine western front and embattled cornice to a land that has been changed by the great industry of the North. As near Saltburn, towards the Tees mouth, is the fine old hall at Marske, built by one of the Pennymans in the days of the First James; at Kirkleatham is the ancient hospital founded by Sir William Turner in 1676, with its museum and a grand library; and the quaint old fishing town of Staithes, still proud of its association with Captain Cook. Kilton Castle, "probably built by Robert de Brus," and the old Priory at Guisbrough, are amongst the most magnificent of the ruins the district shows.

Screened from the east winds by the hills in front, swept by the breezes that blow from the Cleveland moors, braced by the strong winds that come in from the German Ocean, life in the summer-time passes pleasantly at Saltburn. It has no business to disturb it,—it is a town for the health-seeker and for the holiday-maker. It is on the shore, the long expanse of sands stretching from it to the Tees mouth; it is on the verge of the moors, and it looks down on the wooded sides of the pleasure-grounds of the glen. Alike from its streets may be seen the fleets of merchant vessels pressing on the ocean to every country, the mining land where the "stones are iron," and the agricultural and antique part of Cleveland, where Freseburgh's conical hill looks on a scene of meadow and moor such as it has known for centuries. It is the appreciation of these advantages that gives to Saltburn the pre-eminence amongst the watering places north of Whitby; its free fresh air, its quiet, and its commanding views. In the future, when from the south it is more easily accessible, these advantages will be more fully appreciated, and Saltburn will attract the many where it has now charms chiefly for the few, who enjoy its quiet and appreciate the rest it gives.

ASSERTED EVIDENCE OF ORGANIC LIFE IN OTHER WORLDS.

A great modern writer, between whose earliest and whose latest works there exists a contrast more painful than any other that can be cited in the records of literature, imagined that he was able to fix the limits of the knowable,—to define what man could, and what he could never, know. Strong in a conceit of which his own works afforded the keenest condemnation, Comte asserted that man could never know anything whatever of the fixed stars, and should therefore confine his studies of the nightly heavens to the movements of the planets. Not many years passed before the folly of the prediction was proved. The spectroscope was added to the implements of science, and before long Huggins was telling us not only of the chemical constituents of the various celestial bodies, and of their solid, liquid, or gaseous conditions, but of the direction, and approximately of the speed, of the motion of some of the stars,—stars so distant from our world that the figures which express that distance in arithmetical form fail to convey any intelligible idea to the mind.

A little time has passed. We have taken breath after the announcements of Mr. Huggins. The latest signals afforded by the study of the spectroscope are those which promise to give some information as to the nature of light itself, as illustrated by the different behaviour of spectra produced by refraction through a prism, and reflection from what is known as a grating, a set of parallel lines ruled on glass at incredibly minute distances from one another. We have scarcely given attention to the hint that the tail of the last comet, B 1881, gives in the spectroscope the lines proper to the vapour of burning alcohol. And now comes another message from the celestial dominions, a message, if it has been rightly read, more wonderful than any that has been signalled by light: a message,—nay more than a message,—a positive relic of life that has been lived outside the boundaries of our own planet. For such, if the facts stated be substantiated, is the result of the microscopic investigation of certain meteorites by Dr. Hahn, of Tübingen.

We speak, of course, with all the reserve that is due to the repetition of so startling an announcement. The first thing to be done, no doubt, is to ascertain beyond all possibility of question that the substances examined are certainly of meteoric, that is to say of non-terrestrial, origin. As to this the statement that the forms detected, though akin to some known to the naturalist, are yet generically different from any hitherto discovered, is not without weight. There are, it is stated, two sorts of meteorites known. Of these, the first, with which we most of us are more or less acquainted, are exclusively composed of iron. Our readers may, many of them, have seen the enormous mass of pure meteoric iron in the British Museum, a bolt which may explain the origin of the famous black stone at Mecca, or of "the image which fell down from Jupiter." The other class of meteorites, which are relatively rare, are silicious, without any trace of iron. Hydrocarbons were detected by Wochler in an aërolite that fell in Hungary. It was thought that they could only have originated in the decomposition of organic substances, but the credence demanded for the idea seemed to be without the bounds of sober speculation. But even more direct evidence is stated to exist by Dr. Hahn. The silicious meteorites are found generally in the shape of spherical or pear-shaped masses, slightly coloured. Dr. Hahn has made sections of these bodies, which he has subjected to microscopic examination. In sections made parallel to the length are some fibres composed of small polyhedra, presenting the form of an irregular polygon with a radiating appearance. These fibres terminate in a point, and sometimes ramify. They comprise a clearly coloured nucleus, enveloped in a darker substance. Dr. Hahn states that they are composed of fossil organisms. He has called in the aid of Dr. Weinland, who has attempted a classification of the forms, which he compares to those found in the *detritus* of coral rocks. He distinguishes about fifty species of polyps and of algæ, imbedded in silex. If it be hereafter established, first, that the bodies examined are unquestionably aërolites, and, secondly, that the chemical and physical signs of organisation are indubitable, we shall have the first direct proof of the theory which has been so fiercely combated by many worthy men, that the organic life existing on our earth forms but a portion of the great system of planetary or sidereal inhabitation.

The most serious difficulty which to our mind is opposed to the views of Dr. Hahn is to be found in the question whence the fossils in question can be supposed to have come. That corals should exist, like, though not identical with, some of the palæontological corals of the planet Earth, or other planets of the system, would be to our mind highly probable. But how should any such relic be removed from its native world? The most violent mode of ejection of any terrestrial mineral into the air with which we are acquainted is that of volcanic scoriæ and ashes. But though dense clouds of these may cover a continent, shutting out, as we have seen, and as Pliny records on the occasion of the destruction of Pompeii, the light of day, nothing rises more than a few miles from the cone. There is no projection of such an order as to send the emitted body beyond the immediate sphere of the attraction of the earth. Neither do we conceive the possibility of such an eruption, or the probability that water rolled on consolidated fossils, showing no signs of volcanic heat, could be found among the scoriæ. Without at all saying that this objection is unanswerable, we still hold that it is one which must be met by the advocates of fossil meteorites. We admit the existence of interplanetary regions in which matter of various kinds may be now revolving as a sort of planetary dust. But we cannot conceive of the growth and existence of fossil life, even of the simplest type, in such a condition. Again algæ are mentioned, organisms of which, as well as of corals, the home is in the water.

We can, indeed, present the advocates of the fossil meteorites with an explanation; but it is one drawn by imagination from the realms of pure speculation, and we are by no means sure that it will be welcomed by the philosophic German mind. It is this. It is well known that in the planetary space which intervenes between Mars and Jupiter, a blank, where a planet ought to be (according to Bode's law) was long thought to exist. It is now known to contain

numerous planetoids, or small revolving bodies, the relation of the orbits of which has led some astronomers to the idea that they are the fragments of a fractured planet. If they be regarded as the unconsolidated elements of a planet which was never coagulated, we get no help from the thought. But if the idea of destructive explosion be admissible, there can be no reason why water-rolled fossils should not be scattered in the catastrophe; or why, after long wandering in the regions of space, they should not at some time stray within the range of the attraction of our globe, and descend on its surface as meteorites. Very wild, the astronomer may say. True; but how else could they come?

FATAL EXPLOSION AT HIGHGATE.

Steam-boiler explosions, preventible evils as they assuredly are, are familiar to us. Gunpowder explosions recur, at the powder-mills, almost with a calculable regularity. Coal-mine explosions, too, often carry devastation through enormous areas of underground activity, and desolation through a county or a province. Water explosions now come to add a new item to the list of terrors,—or rather, as water is neither an explosive substance, nor even an elastic fluid, an explosion the destructive energy to produce which has been accumulated by the silent energy of water.

A reservoir belonging to the New River Company is situated on ground above the Highgate Archway. Its capacity is such as to hold about six million gallons of water, which is pumped up from the great filtering-beds of the company in the neighbourhood of Hornsey. On the closed system of pipes was fixed an air chamber of wrought-iron, about 6 ft. by 10 ft. in height. On the afternoon of the 16th of August this suddenly flew into the air, wrecking a part of the buildings, and killing William Langden, the engineer, who was found in an insensible condition under the *débris*. A disaster of so unusual a kind demands the most anxious inquiry. We do not say this by way of attributing hypothetical blame to any one. The works of the New River Company are under the watchful and competent control of an engineer whom his brethren must approach rather as learners than as critics; and we are confident that the more minutely his arrangements are inquired into, the more thoroughly will this prove to be the case.

But the civil engineer never leaves school. To keep up to the demands of his noble profession he must ever be a learner. He must be a learner from nature, from the counsel and experience of his contemporaries, and, above all, from any new and strange disasters. In the present case we are anxious that the mechanical elements of the case should be exhaustively ascertained. The fractured air-vessel should be subjected to a most careful observation, not only *in situ*, but with the aid of the microscope, and of chemical analysis applied to fragments of the metal; and the maximum force which, whether from gravitation or from direct engine-power, could be exerted at the spot, ought to be distinctly ascertained.

The question presents itself for discussion, how far is it advisable to allow of the introduction of a closed air-chamber in a system of closed water-pipes? We confess that the recent explosion (speaking with due hesitation and reserve) seems to confirm our own opinion that such an element is inadmissible. There are two methods by which water may be made to rise to the top of the buildings of a town. One is by pumping it to the top of a commanding eminence, and allowing it to descend and rise again by gravitation. The other is by direct forcing into a closed system of pipes. We have no hesitation in saying that the first method is by so far the safest, most certain, and most satisfactory, that in any case where the character of the country allows, it ought to be adopted, even if at the expense of much additional main-pipe. But where the closed system is unadvisable, it may be thought that the introduction of air-chambers will not only allow of the disengagement of air forced into the mains together with the water, but further serve, not as a safety-valve, but rather in the way of a fly-wheel, in giving elasticity to the pulsation of the system. As to the first object, we can speak from practical experience of a town where the water, being raised to a commanding level, whence it descends by gravitation, flows into the mains so full of air that it resembles milk rather than water when drawn from a tap. But the milky fluid is of exceptional purity. If left to stand in a glass jug it immediately begins to clear, not, as is the case with muddy water, from the top, but from the bottom. Little bubbles ascend like foam, and in twenty or thirty seconds the water is perfectly clear and pellucid. No doubt the air mechanically mixed with it is an advantage rather than the reverse.

As to the use of air as an elastic cushion, the recent event seems to indicate that it is an unnecessary source of danger. Of course the pressure at any point cannot be increased by the fact that it is transmitted from a non-elastic (practically speaking) to an elastic fluid. But the mode in which that pressure will behave, if anything should give way, is totally different, according as it acts on the one or on the other medium. The rupture of the air-chamber in the recent case proves that a force was applied of sufficient power to rend the metal. If that force had been applied (as in proving tubes) by hydraulic pressure, the iron plate would have torn when its cohesion was overcome, and there would have been an end. But the introduction of the elastic fluid makes this difference; the moment the plate begins to crack or to tear, instead of adequate relief being administered to the tearing power, the elastic force follows up its victory, and, expanding as it overcomes resistance, converts a fracture into a burst, a crack into an explosion. We very much doubt whether any sound reason exists to justify the encounter of such a source of danger. As to this, however, we hope that the disaster of the 16th will elicit an expression of the opinion of the most experienced hydraulic engineers of the day. We commend the subject to the attention of the Institutions of Civil and of Mechanical Engineers.

BUILDING MATERIALS IN THE SIXTEENTH CENTURY.

The amateur theatrical performance recently held, under Royal patronage, in the great hall of Hampton Court Palace, has attracted not a small amount of public attention, and the weekly picture-papers have not disdained to devote their artistic consideration to the conspicuous representation of the scene which the old hall presented on the revival of the memories of its old glories. The Great Hall of Hampton Court Palace, incorrectly termed the "Wolsey Hall," for it was built some years after the famous cardinal had handed over his palace to his master, Henry VIII., holds architecturally an interesting place in the art history of the country. It is familiar, from numerous representations, to many who have never had the good fortune to visit Hampton Court. But a further professional interest is connected with the Great Hall of Wolsey's Palace. We possess detailed accounts of the expenses of its erection, such as are in very few cases to be found. These details relating to the price and quantity of materials used in the erection of the hall are carefully preserved in the Public Record Office; but, practically inaccessible there to the public, they will be found published at length in the excellent "Guide to Hampton Court," written now many years ago,—and, we believe, at present out of print,—the work of "Felix Summerley," now known to the world as Sir Henry Cole, K.C.B., the energetic director in its early struggles of the South Kensington Museum.

We take the opportunity, as an appropriate one, of the public interest recently aroused by the amateur theatrical performance in the Great Hall of Hampton Court Palace, to lay before our readers a portion at least of the curious details in the original account of the building of the hall, "anno 23 Henry VIII." (1532, an interesting year as that following the acknowledgment of the King as "supreme head of the English Church"). Some comparisons by those familiar with the prices of the similar building materials in the present day will be interesting to make, over the 350 years' lapse of time. It may be stated of the comparative value of the sums mentioned, that, taking the standard of the current price of corn then and now, the sums of the time of Henry VIII. would require an equivalent of some eight times their value in the latter quarter of the nineteenth century.

The original Hall of Wolsey's Palace having to be pulled down, the first item on the accounts refer to the sums thus expended:—Freemasons at 3 shillings a week, "every of them working in frestone uppon doors, wyndowes, &c."; carpenters at sixpence a day, "joyners" paid at the same price; in pulling down the hall, every "sawer of tymber" paid at 12 pence the 100 ft.; carpenters for "framyd scaffold," at 6 pence a day; "tylers" taking down tiles, 8, 6, and 5 pence a day; labourers, 4 pence; "setters" "to take down freestone, 3 shillings and 8 pence a week each; and carpenters sorting the timber of the roof, 8, 6, and 4 pence a day. In the building of the new Hall we have the items of the purchase of the implements and materials, mattocks, "scaffold poles"; "10,000 of bryke," paid for at 4 shillings and 6 pence "the thousande"; carters from the brick-kiln at 14 pence a day; "lodes of lyme reddy burnyd," at 10 pence a quarter; chalk at 2 pence a load; "plaister of Paryshe" at 6 shillings "the maunghte"; "Rygate stone," at 4 shillings and 2 pence the ton; "hand ropes to rere the rouff of the New Hall," 29 lb. at 2 pence the lb.; and "six crowys of irone to raise the rouff," at 1½ pence a lb. Bricklayers, "every of them," at 6 pence a day.

The masonry work we find paid for by "the pece," and, of course, the prices vary according to the nature of the work; the same is the case with the carving in stone and wood. In the smiths' work, "barres" standards for windows, for each hundredweight (of 112 lb.), 1½ pence the pound, the price at which all the iron quoted seems paid for. There are some curious items respecting the nails used; 7,350 "dubbyl tenpenny nayles inglys," at 11 shillings the 1,000; 3,800 "myddil bradds" at 12 pence the 100; 2 shillings the 100 for "great bradds; 2,000 "twopenny nayles," at 10 pence the 1,000; 2,000 "syngle tenpenny nayles," at 5 shillings and 8 pence the 1,000; 12,000 sixpenny nails at 2 shillings and 6 pence the 1,000; 5,000 fivepenny nails at 2 shillings and 10 pence the 1,000; 4,000 fourpenny nails at 2 shillings and 4 pence the 1,000; and 1,500 "rought nayles" at 10 pence the 100.

In the item of carpenter's work we find mention of "sesyned playnche," at 3 shillings and 2 pence the 100; 2,000 "fine bourddes," at 31 shillings and 13 pence the 1,000; six "payres of scruse" at 5 shillings and 2 pence "the payre." The plumbers' items quote lead at 4, 7, and 8 shillings the "fother"; "sowther" at 4 pence the pound, "for sorderyng the pypys abowght the kyng's New Palace."

The items for the payment of glazier's work (*anno* 25 and 26 Hen. VIII., 1534-35), speak of "8 panys, new sett, 54 feet, at 5 pence the fote;" the stained and painted glass, with its armorial bearings, is, of course, paid by the piece, but all quotations of plain glass are at 5d. the foot. To pave the hall we see that there were required 6,080 "playne tyles" at 28s. 8d. the 1,000. There is a curious item of "tallow candells" burnt during the night-work, and paid for at 1s. 6d. the dozen; "paving tyles" at 13s. 4d. the 1,000. The contract for paving the hall amounts 53s. 4d.

The painter and gilder's work is paid for by the piece, as might be imagined, and many of the items mentioned,—a detailed description accompanies each,—may be recognised to this day still in their place. We meet here with a general item for four of the "king's words in Gryke letter, with fyne golde gylte," paid for at 2s. the word; a hundredweight of red lead "for the barres of the hal windowes," 13s. 4d.; and a "pottell of paynter's oyle," 1s. 6d. a gallon; 12 pounds of white lead at 2d. per pound; red lead, at 2d. To a painter of posts (white and green) at 1s. 4d. the yard; and again for painting "badges of the king, gilt with gold and bysse," and other colours, 21s. the yard.

We again come upon the item of "fremasons," this time at 12 pence a day; the "warder," 5 shillings a week; "setters," 3 shillings and 6 pence a week; "lodgman," 3 shillings and 4 pence a week; "hard hewers" 3 shillings and 4 pence. Among the carpenters the master is paid 12 pence a day, the "warden" at 8 pence, the rest, as apprentices, 4 pence to 8 pence. Among the bricklayers the master receives 12 pence a day, the "warden" 8 pence, the rest 7, 6, 5, and 4 pence. The master "joyner" receives 10 pence; the rest 7, 6, and 4 pence; the master "paynter," 12 pence; the grinder of colours, 5 pence a day; the master plasterer, 8 pence; the "serviters," 5 pence; the "plummers," 5 pence to 7 pence a day; the "sawyear," 12 pence a day; "scaffolders" at 6 pence a day; the carters at 16, 14, and 12 pence; the labourers at 4 pence.

A number of other items are given, but in no

way connected with the building of the hall. Those who are curious on such matters we again refer to Felix Summerley's "Guide to Hampton Court; its Architecture, Tapestries, Paintings, Gardens, and Grounds."

THE TIMBER TREES OF NORTH SCANDINAVIA.

A LECTURE on "The North Scandinavian Forests and the Wood Trade" was delivered by the Rev. G. Liljeroth, at Albion Hall, Londonwall, on the 16th inst. The lecturer, after some introductory observations, proceeded to define the geographical extent of the forests of Scandinavia, observing that, except a belt along the northern coasts of Norway and Sweden,—*i.e.*, on those parts of the coast between the latitudes of 66° and 72° N., pine-trees grow all over the peninsula. It was his intention, however, to confine his remarks to the North Scandinavian forests, especially those of Sweden. The trees found nearest to the Arctic regions stand alone on the southern slopes of high hills, which protect them against the northern wind. Travelling southward, the explorer would find that as the intensity of the cold diminished the number of trees increased, until at last they formed vast forests. As the whole of Lapland had not yet been fully explored and mapped, it was impossible to state the exact extent of its forests. It might be stated, with tolerable certainty, that the forests of the North of Sweden covered an area of about 17,000,000 Swedish acres, and if the Norwegian forests of Nordland and Finnmark were taken to cover about the same extent,—as was probably the case,—the sum total was an area of 34,000,000 of Swedish acres of forest. This estimate was certainly not excessive, and perhaps it was insufficient. It was not without reason that Swedish iron and Swedish fir had been sought for everywhere. A journey through Scandinavia from the North of Sweden to Denmark would enable the traveller to note the changes in the character and appearance of the trees as he travelled southward. In the most northern parts of the country the trees seemed to have a struggle to eke out an existence; but as the southern part of the country was approached, they became mighty monarchs of the forest. Nothing was more edifying and impressive than a walk through one of the typical forests of North Scandinavia. It was not to be wondered at that the forests had been regarded by the people as holy. The North Scandinavian forests were capable of affording the largest and best supply of timber. The forests in the south were getting used up, and did not seem to have a bright future before them, owing to the wastefulness which was constantly going on. Whole tracts of forests were sold, and the trees cut down, at haphazard almost, and without any settled plan of replenishment. Formerly forest lands were acquired under conditions quite different from those which now obtained. Many people who had amassed such large fortunes as to enable their children to become magnates, had acquired their wealth through having obtained forest property in an improper way. At the present time, however, the timber merchants of Sweden had to buy the forest ground, at great cost, and there was great competition for Crown forests when put up to auction. Cutting-down was going on with undiminished vigour without due provision for the future, and as forests were essential not only to the prosperity, but to the very existence of the inhabitants, the outlook on the future of the country was not a very bright one. The Scandinavian timber-hewer,—the actual worker in the woods,—was necessarily a strong and healthy man. Before he started for the forests he had to prepare and take with him provisions for two months. His bread was made and baked in thin round cakes or sheets as large as carriage-wheels. These were doubled together and put into a sack. The woodman's other food, consisting of herrings, potatoes, butter, cheese, pork, &c., was also put into sacks. The corn-brandy bottle was carried in a more handy and accessible manner, as was considered necessary, owing to the fact that the woodman, in his journey through the forest, made it his duty to have a drink every time he arrived at a suitable tree,—and it was astonishing, said the lecturer, how many "suitable" trees he found on his journey. When a party of hewers arrived at that part of the forest which was to be the scene of their labours, the first thing that they did was to provide themselves with a hut for living in, leaving a hole in the roof for the smoke from the fireplace to pass out. The fireplace consisted of a few stones in the middle of the floor. Round the walls of the interior of the hut, and about level with the fireplace, were fixed broad shelves, so broad as to allow of the inmates sleeping on them with their feet towards the fire, the fire being made so as to burn all night long. Early in the morning, when the men arose from their slumbers, kettles containing potatoes were placed round the fire, and frying-pans containing meat or fish upon it. Knives and forks were not used. Every man helped himself with his fingers, which were already covered with resin, soot, and other matter,—dirt of some standing. After the men had made themselves sufficiently comfortable by means of warmth and food, out they went into the intense cold to their work,—a work attended with many dangers, for often a falling tree would get entangled in the branches of another tree, and the work of disengaging it required a great amount of intrepidity, quickness, and daring. The pay of the timber-hewer was very small. Although he worked from early in morning until late at night, he seldom earned more than 1½ or 2 Swedish crowns a day. The removal of the fallen trees from the forest was usually accomplished, in the first place, by horses. Beautiful as those animals were when they went into the forest in the autumn, in the spring they emerged in a most dilapidated condition. When the roads were bad the poor animals suffered fearfully, and they were often beaten shamefully. At times they had literally to wade in snow, and at other times they had to drag their sledges over sand and stones. In going over large stones they had a jumping style of motion, in order to get free of the trees they were drawing. When the trees arrived at the watercourses they were floated down. The work of a floater was both amusing and dangerous. Very often a single log would place itself across the stream, and so prevent the passage of thousands of logs. The mass of logs accumulated through this obstruction could only be liberated by cutting away the obstructive log. No one was compelled to perform this dangerous work, but somebody sufficiently daring generally volunteered to cut away the log. The logs behind, in consequence of the rapidity of their descent down the streams and over the waterfalls, mounted one upon another, until there was an enormous mass of timber waiting to be set free from the obstruction. When a few cuts of the axe had been made at the obstructive log, it crashed through by the force behind it, and then woe be to the wielder of the axe unless he was as fleet of foot as a cat. The work of removing the fallen trees from the forests often rendered it necessary for the men to sleep out in the open, in the midst of snow and ice, all night. That would not be possible but for the fact that they were able to build a fire of logs which would not only burn all night, but far into the next day. The men lay with their feet towards the fire. The work of floating was in some respects very detrimental to the population, for, for the sake of earning extra wages, many engaged in it who, owing to the shortness of the spring, could ill be spared from the work on the farms. The worst of it was that many of the men were not only none the richer for their extra earnings, but eventually a great deal the poorer, for they spent their extra earnings in drink, and led such a riotous life that they unfitted themselves for steady application to work in the future, and they returned to find their homes neglected and their characters blasted. The saw-mills, which were now mostly worked by steam-power, were for the most part situated on the mouths of the rivers on the most suitable parts of the coast. The saw-mill owners were, as a rule, a well-to-do body of men, living in houses having ten or eleven rooms, whereas very often the workman had only one room for himself and the whole of his family, which room had to serve at once as kitchen and bedroom. The relations subsisting between the mill-owners and the workmen were not of the best. When the men complained of smallness of wages, and sought for more, they were taunted with such extravagances as wearing overcoats and goloshes, and carrying umbrellas, to say nothing of drinking Champagne, going to "Temperance and religious meetings," and otherwise "throwing away" their money. The men, on the other hand, when the mill-owners informed them that badness of trade compelled them to reduce their wages, retorted on the masters by saying that hard as they alleged the times to be, they did not live less luxuriously or eat less expensive dinners than in more prosperous times. Thus there was continual recrimination between masters and men, and this was the cause of the Sundsvall strike a few years ago, which had been productive of a great deal of damage to the trade of the North,—and unfortunately the repressive measures of a military character which were taken had made matters worse. The king recognised that, and, over-ruling the local authority, ordered the withdrawal of the troops. Unfortunately, the strike in question had left many evils in its train, and one of them was the tendency towards Socialism and irreligion which was found amongst some of the working people. Although vast areas of forest had been cut down, and much of it burnt or wastefully destroyed, a very great deal remained,—some of it almost impassable owing to its density. But the requirements for home consumption and export were very great. For home consumption, over 96,000 standards of timber were used every year for making corn-brandy alone, independently of other home needs, while 718,000 standards were exported. Even with this large consumption and export, however, the forests of Scandinavia would be equal to the demand upon them, provided that they were properly conserved and protected. At present a great deal of damage was done by wounding and stripping the trees for the sake of getting tar. This was carried on with great and reckless waste, and the trees, being allowed to stand in their mutilated condition, prematurely withered away and died. It was hardly possible to imagine the melancholy appearance which some parts of the forest presented owing to this mutilation of the trees. If a suitable machine could be devised for economically and expeditiously removing the stumps of the trees which had been cut down, this mutilation would very soon cease, as the stumps, which really contain the material most serviceable in making tar, would be profitably utilised instead of being, as hitherto, wasted. In the northern parts of the country a great deal of damage was done to the trees by taking off the bark for food for goats. The best and most sappy trees of the forest suffered from this cause. Millions of trees of the finest promise had been destroyed owing to these injuries. Forest fires, which were of frequent occurrence, also wrought terrible havoc. Some of these fires were, it was to be feared, the result of malicious acts, but the majority of them were the result of accident or carelessness on the part of the woodmen. When a fire broke out in the forest everybody in the vicinity was bound to help to stay the disaster. This was commonly done by clearing a space round the area of the fire by cutting down the trees, a process which had to be repeated over and over again when strong winds were blowing. A tract of burnt-up forest presented a fearful sight. Happily, the nation was awaking to the importance of conserving its forests, and schools of forestry were everywhere springing up, and increasing the number of their pupils. An organised system of inspection had been established. Every year plenty of forest seed was sown. In one recent year Sweden had 1,375 planting schools, which were the means of planting 3,589 lb. of seed. This year 4,462,668 plants had been planted. In this way the nation was doing a great deal to keep the forests alive, although rather late in the day. It should be remembered that it was a long time before the best trees came to maturity. Some of them needed to grow for 250 years before they were fit for felling and sawing. It would thus be a long time before the forests now being recuperated would be ready for the axe of the hewer. In conclusion, the lecturer referred to the honourable dealing which he said was characteristic of the English wood-merchants, and expressed the hope that the pleasant relations which now subsisted between them and the Swedish merchants would remain unimpaired, to the advantage of the trade of both England and Scandinavia.

Mr. Liljeroth, whose interesting lecture, delivered in the Scandinavian tongue, was interpreted to the meeting, was accorded a vote of thanks.

Surbiton Cottage Hospital.—The first premium for plans for a cottage hospital at Surbiton was awarded by the committee to Mr. Ernest Carritt, 4, Lime-street-square, London; and the second premium of 10*l.* to Mr. Loxwood King, of Surbiton.

DAMP: ITS CAUSES, EFFECTS, PREVENTION, AND CURE.

Under this title M. G. Philippe, a civil engineer officially employed by the municipality of Rouen, has contributed to *Les Travaux Publics* a series of valuable and interesting papers, of which we reproduce the principal points. The subject is of universal and individual interest, and of even greater importance in the climate of England than in that of France.

The *causes* of damp in buildings are,—1, the presence of water in the atmosphere and the soil; 2, the porosity of building materials, which absorb it.

Its *effects* are only too well known, and may be classified as,—1, disintegration of masonry, with injury to wall-papers and other similarly-placed decorations; 2, decay of timber, and injury to wooden furniture; 3, development of saltpetre on walls, with injury to wall-decorations; 4, injury to health of inhabitants.

The decay of the timber used in building often carries with it an especial danger in France, because there chesnut-wood is frequently employed for large beams; and as this wood decays first at the heart, while the outside remains sound, no superficial examination will give warning when an important piece of timber may be about to give way.

The development of saltpetre results from drying after damp. It is well known that this substance can be obtained from old building materials, and the white patches which it forms upon perfectly sound walls are familiar. During the siege of Paris, in 1870, the possibility of utilising it for military purposes was taken into consideration, and a committee was appointed to investigate the amount obtainable in this way in case of necessity. It reported that the production of saltpetre in a building was in direct proportion to its age and uncleanliness. This conclusion appears very obvious, when we remember that saltpetre consists of potash, combined with nitric acid, and that nitric acid is azotate of ammonia. Kuhlmann, a distinguished chemist, proved by experiment that ammonia contained in a porous body is oxidised by contact with the air, and becomes azotate of ammonia. Fermenting vegetable and animal matter everywhere furnishes ammonia, building materials are the porous body required, and all clays contain potash; so that all the component parts of saltpetre are ready to hand, and as soon as the moisture which has held it in solution is evaporated by drier air, the salt appears upon the surface. It is not necessary that ammonia should be present in any offensive form; rain will contain it, and fogs (especially town fogs) carry it in comparatively large quantities.

The prevention and cure of damp may be attempted by:—(1.) employment of suitable materials for cellars, and other parts of buildings below or on the level of the soil; (2.) damp-courses to stop the upward progress of damp; (3.) preparations of different natures, either to protect the face of an exposed wall from the weather, or to prevent damp in the wall from affecting an apartment; (4.) precautions against infiltration.

The most thoroughly sanitary foundation for a building is concrete; and the author recommends covering the whole level of the future building with a layer 4 in. thick, composed of two-thirds broken flints well washed, and one-third mortar made of lime and gravel sand. He estimates that such a layer would cost about 2½d. per square foot.

Well-puddled clay forms a good and inexpensive foundation, in districts where it is easily obtained. A layer 8 in. thick should be spread over the site of the building, and extend for about 16 in. outside the walls; and the external 16 in. should be carried up with the wall until the level of the soil is reached. Clay cannot, however, be used to form a dry flooring for old buildings, as can be done with concrete.

Various methods have been proposed and employed for destroying that porosity of building materials, which is one of the chief causes of the mischief. M. Sébille, a civil engineer in Paris, has patented a process for injecting materials (especially brick) with gas refuse, which penetrates their substance, and renders them impermeable by water, at the same time increasing their weight, and giving them a brown colour. A wall built with bricks thus prepared is absolutely dry, and their price is only increased by about 3s. 4d. per 1,000. Good results have been obtained by immersing the materials in solutions of soap and alum successively, and by applying these two preparations to the thoroughly-scraped surfaces of the walls of buildings already standing. The result of the chemical reaction which follows is to fill the pores of the brick or stone with a fatty substance, which opposes the passage of water. The immersion costs about 1d. per cubic foot of material.

The method preferred by M. Philippe is to plunge the material with the hand into a solution of silicate of potash for a time, merely long enough to allow all the air-bubbles to disengage themselves from its surface, and then to lay it aside for forty-eight hours before using. The additional expense is extremely small, and the results (according to his experience) very satisfactory.

Many varieties of cement and other material are employed for mixing with mortar, in order to render it impermeable by water; of these the principal are Vassy or Gariel cement, Vicat (from Grenoble), Portland, French Portland, and Peterspense cements, ground brick, Pozzolana (volcanic), wood ashes, calcined oyster-shells, &c. The greatest additional expense from using any of these is from 3d. to 7d. per cubic foot of masonry. A layer of such cement 1 in. thick, lining the walls of cellars, &c., is very useful, and costs on an average a little over 3d. per square foot. M. Philippe does not recommend French Portland cement, which is prepared chiefly at Boulogne, and which is much used in the North of France, as it very imperfectly excludes damp, and is easily penetrated by saltpetre. Of French cements he prefers the most expensive,—that of Vassy. For application to damp walls, solutions of soap and alum, used one after the other, have already been mentioned. Another substance which has proved useful for the purpose is gas tar. The wall must be well scraped, heated in parts by means of a hand-stove, and the tar applied with a brush as hot as possible. It then penetrates into the pores, and hardens in cooling, forming a crust which arrests the passage of damp and saltpetre. The cost is very trifling.

An important and interesting piece of work of this kind was performed about the year 1813, under the direction of MM. Darcet and Thénard; and as their methods have not been surpassed, we quote a portion of their own account, extracted by M. Philippe from vol. 32 of the "Annales de Chimie et de Physique":—

In that year, "M. Gros undertook to paint the upper cupola of the Church of Sainte Geneviève. The surface had been prepared like a canvas, with a layer of strong size, covered with white-lead mixed in drying oil. M. Gros consulted us upon the durability of this composition, and we did not hesitate to declare that it was far from offering the desired security against damp. After consideration and experiment, we adopted the following method. All the previously-applied preparation was entirely removed; portions of the interior of the cupola were then successively and highly heated by means of a large gilder's stove, and our preparation applied with large pincers, at a temperature of about 212° Fahr. To facilitate its absorption, the wall was re-heated once or twice during the process. Successive coatings were applied until no more could be absorbed. When dry, a coating of white lead mixed in oil was superposed, upon which the painting was to be executed. The preparation used consisted of one part of wax and three parts of boiled oil, with one-tenth its weight of litharge. The heat employed must merely stop short of carbonising the oil."

The same process was applied by its inventors to two damp underground rooms at the Sorbonne. The mixture was slightly different, consisting of one part oil prepared with litharge, and two parts resin melted in the oil,—an operation of some delicacy. The plaster was allowed to remain on the walls, and they were thoroughly dried with a gilder's furnace, which, by an ingenious arrangement, was made to move along the wall at a fixed distance from it, and at any height. When dry, they were again heated for the application of the varnish, as in the preceding case. Five coatings were absorbed; the sixth was partially absorbed, and formed a smooth hard surface to the wall. The cost of the process is chiefly that of the labour; the value of the materials being about 1d. per square yard.

M. Philippe proceeds to make suggestions and give opinions on various points of detail, some of which we reproduce.

Parquets may be preserved by laying them upon bitumen. This invention was patented by M. Gourguechon, but his patent has expired. It has been successfully varied by laying down a well-smoothed bed of cement, then applying a thin layer of asphalte to a portion at a time, and laying down the parquet before the asphalte had cooled. The only difficulty with these methods is that they cannot be used with pieces of parquet much exceeding one yard in length. The frames by which the parquet is held should be fastened to rows of spaced bricks, and the intervals filled up with pebbles, cinders, or other dry and healthy material, avoiding sawdust, old plaster, and similar matters.

Ventilating Bricks on the Flagedé system may be made on the spot in a mill supplied by the inventor, at the rate of from 300 to 400 per day, of almost any materials that may be at hand,—plaster, conglomerate, brick-earth, even of *torchis* (clay mixed with straw and grass). They admit air to the interior of the walls, and thus keep them dry. Their size is double that of bricks, and their price comes to about 1l. per 1,000.

The *Journet patent* for dry floors or areas consists in laying down a bed of cement about 2 in. thick, in which small pipes are laid at about 1 in. apart, and then covered with another 2-in. layer. When the cement begins to harden, the pipes are drawn out by the end, leaving hollow tubes, through which the air can circulate, if proper openings are provided in the walls.

Silicate applied to the surface of buildings renders them almost impervious to the action of weather. It has been applied by M. Kuhlmann to the principal monuments in the town of Lille, and to the new buildings of the Louvre in Paris, with the additional good result of harmonising their tone with that of the older portions. It costs about 10d. per square yard, for three successive applications at twenty-four hours' interval. M. Mignot has invented a cheaper preparation, coloured to suit the different kinds of stone. It is to be noted that silicates cannot be used upon walls where saltpetre has been or is likely to be developed.

Enduits have been invented in great variety by different makers. A very excellent one, called Glyko-metallic liquid, is prepared by MM. Caron et Dupuis. It prevents all action of damp on cement and plaster, by neutralising the alkaline salts which they contain, and can be painted on with perfect security. Old walls should be well cleaned before it is applied; new ones will require three coats, which will cost about 9d. per square yard. An excellent preparation of gutta-percha is supplied by the Maison Gaudri, in Paris, for the same purpose, and costs about the same price.

Windows are one of the principal avenues of damp into apartments. One cause of this is the bad quality of the stone often employed. It should be as hard as can be obtained; or it might be covered with zinc, or coated with a good cement. Small leaden gutters may be placed inside the windows, to catch and carry off the rain which penetrates. This plan is particularly recommended for the windows of kitchens and bath-rooms, where the steam condenses on the glass in considerable quantity.

For *slates*, M. Philippe recommends either the Fourgeau or Chevreau system of hooks in preference to the ordinary method of nailing,—which makes a hole through which damp penetrates.

Drains from closets should be furnished with a ventilating-pipe, carried up with the chimneys, or which may (as at the Hôpital St. Louis and the old Hôtel Dieu at Paris) open direct into the kitchen flue, thus being always secure of a strong upward draught. In this way all unpleasant smells are obviated.

Mr. Gladstone's Chair.—The chair presented by the Greenwich Liberal Association to the Right Hon. W. E. Gladstone, M.P., on the 17th inst., was manufactured by Messrs. G. S. Lucraft & Son, of the City-road. It is made of brown oak, the covering being in buff morocco, finished round the edge with Westminster blue banding and silver nails. In the centre of the back, embossed in gold, are the arms of Mr. and Mrs. Gladstone. The carving on the top of the chair, in the form of a wreath, includes the rose, shamrock, and thistle, and leeks, in the centre of which is the silver inscription-plate. In the panels on each side is an axe. The panel under is emblematical of Despotism on the one side, and of Liberty on the other, with the All-Seeing Eye in the centre. The chair runs on silver castors, and there is a footstool made to match. In design it is a good square sound chair, and creditable to all concerned.

SANITARY EXHIBITION AT EASTBOURNE.

An exhibition, principally of sanitary appliances, but also including objects of art and articles of domestic utility, was opened on Monday last in the Devonshire Park Pavilion, Eastbourne. The exhibition, which originated from a suggestion of the Surveyors to the Local Board (Messrs. C. Tomes & E. W. C. F. Schmidt, A.R.I.B.A.) and Mr. J. T. Rodda, has for several weeks past been looked forward to with a considerable amount of interest. The public men of the town heartily co-operated with the three gentlemen named; his Grace the Duke of Devonshire consented to become patron of the exhibition; and Dr. G. A. Jefferys (chairman of the Local Board) accepted the post of President. The promoters of the exhibition state that it is a well-known fact that Eastbourne is the one town in England where all sanitary matters are attended to perfectly, and having proved the benefits of proper sanitation themselves, they are desirous of sharing them with their visitors and giving them an opportunity of seeing and hearing for themselves what sanitary science can do. With this end in view they have, besides providing the exhibition, arranged for a course of popular scientific lectures, two of which were given on Monday, the others being given on subsequent days of the exhibition. The lecturers on Monday were Mrs. F. Johnstone and Dr. Alfred Carpenter; on Tuesday evening Professor Robert Kerr delivered a lecture; on Wednesday there were two lectures, one at four and one at eight,—the evening lecture, by Mr. E. C. Robins, F.S.A., F.R.I.B.A., being on "The Revelations of Sanitary Science," and the afternoon lecture being by Mr. A. M. Mowbray, F.R.I.B.A., whose subject was "How home can be made attractive and healthy."

At the opening ceremony the President (Dr. Jefferys) officiated, and in the course of his address said that amongst all the objects which he saw around him it would be very difficult to descant upon one particular exhibit; but having seen the programme, he was greatly struck with the title of a lecture to be delivered on Friday by Mr. Schmidt. The title was a very extraordinary one, "How not to build a House." He hoped he should not be encroaching upon Mr. Schmidt's domain if he said a few words on the way in which he (the speaker) considered a house should be built. A house, he took it, should be a building in which a person or human creature might dwell, and unless such a house possessed certain essentials, it would be a dangerous place to dwell in. In his opinion the essentials necessary were, that it should have a good situation, be well-built, be situate in a broad street, have rooms well aired and well ventilated, and be bountifully supplied with pure water,—be replete, in fact, with every sanitary appliance; and, above all things, well and efficiently drained. A town was a crowd of houses, and if each house possessed all the essentials he had mentioned, that town would be a healthy place, and would afford pleasure to those who took up their abode in it. They rejoiced to have a town possessing many, if not all, the essentials he had mentioned in his ideal house. Eastbourne was well placed, and sheltered from the prevailing winds by the glorious Downs. The houses were well built and situate in broad streets, beautifully planted with trees growing luxuriously, which made the town picturesque and beautiful. Apart from this, they were open to the great expanse of sea, which tempered their climate, and the breezes from which not only produced salubrity in the town, but imparted to it a bracing atmosphere. Amongst their 25,000 inhabitants, he trusted there were many who would come and see for themselves the exhibition which those present saw around them, and he was sure they would go back with new ideas, the carrying out of which would benefit their neighbours and the town in which they lived. He would ask, also, that employers of labour should send their artisans to the exhibition, feeling sure that the employers would benefit from the knowledge acquired by their men; he would ask parents to bring their grown-up children; and he would ask masters and mistresses to allow their domestic servants to attend, believing that they would derive such knowledge as would tend to make home comforts more pleasurable. Finally, he would ask all those who could to come, being sure that the end they had in view was to increase the pleasure, promote the health, and prolong the lives, not only of Eastbourne people, but of visitors who frequented that health resort of theirs. In conclusion, he declared the first exhibition of sanitary appliances ever held at Eastbourne duly opened.

The opening ceremony thus ended, visitors commenced a tour of the exhibition. The stands in the pavilion, thirty-nine in number, are arranged around and in the centre of the room. The first stand is occupied by Messrs. Doulton & Co., Lambeth, who show many specimens of art pottery, but whose speciality is their new Silicon ware, for which they claim that it is free from the objections belonging to the high glaze of ordinary pottery, and the porosity and fragility of terra-cotta. Mr. D. T. Bostel, of Brighton, exhibits his Brighton "Excelsior" closet, and other articles. The stand of another local exhibitor, Mr. J. A. Skinner, of Eastbourne, covers a considerable space; he has on view several specimens of closets, cisterns, and ventilators, as well as traps and smoke-preventing chimney-pots. A stand of a similar character, the proprietor of which is Mr. F. G. Underhay, of Farringdon-road, London, adjoins Mr. Skinner's stand; and next to this Messrs. Doulton & Co. have a second stand, at which they exhibit water-waste preventers, bath apparatus, filters, and other sanitary appliances, in action. Messrs. Fredk. Walton & Co., Berners-street, London, exhibit specimens of the Sunbury non-poisonous wall-decoration, in a variety of good patterns. Samples of concrete chimney-pieces, paving and moulding slabs, may be seen at the adjoining stall, occupied by Mr. W. H. Lascelles, of Bunhill-row, London; the Silicate Paint Company have the next stand; and following this is a stand occupied by Messrs. S. & E. Ransome, Strand, London, who show their patent solutions for the cure of damp walls and for preserving stone from decay, and specimens of tile and stone work dressed with these solutions. Concrete tubing for drainage purposes, improved gullies and stoneware pipes, with the Stanford joint, from the Bourne Valley Pottery, Poole, comprise the exhibits at the adjoining stand; and at the next Messrs. Wilcock & Co., of Barmantofts, Leeds, have a fine show of glazed bricks in every variety of colour, architectural faïence, red and buff terra-cotta work in many designs, among them models in foliage and fruit, and sanitary specialities in the shape of patent gullies, flushing tanks and traps, irrigation conduits, sewer ventilators, &c. Another of Doulton & Co.'s stands, at which are to be seen terra-cotta mantelpieces with patent fire apparatus, terra-cotta fenders, hearth tiles, drain-pipes with patent joints, intercepting traps, latrines and urinals, and many other things of a like nature, follows; and at the succeeding stand, occupied by J. C. Ellison, of Leeds, are that gentleman's patent ventilating appliances. The Papyrotile Company, with specimens of a newly-patented and effective wall-tile for decorative purposes, come next; then another stand of ventilating sewer and gully traps, closet pans, &c.; and next Messrs. Robert Boyle & Son's, of London and Glasgow, at whose stand the well-known Boyle's patent self-acting air-pump ventilators are on view. Besides all these there are in the room a stall at which Banner's patent ventilators are shown; another at which can be seen working models in glass of Shone's patent pneumatic ejector as now being applied in the sewerage of Eastbourne; and Mr. C. E. Zimdars's stand of pneumatic bells, indicators, pulls and pushes, and pneumatic door-catches. The pavilion itself contains all the stalls enumerated, and the annexe an equally large number. In fact, the annexe is even more interesting than the exhibition in the Pavilion itself, for in this department almost everything is at work, and practical illustrations are thus given of the utility of the various exhibits. Closets and lavatories of every description, filters and stoves, pottery, cooking ranges, patent window sashes and fastenings, ventilators, gas-burners, lamps, butter-making implements, are among some of the contents of the stands here. Certificates of merit are to be granted to the most meritorious of the exhibits.

Volunteer Sanitary Work.

The audience at the afternoon lecture on Monday, delivered by Mrs. Johnstone (Manager of the Hastings and St. Leonards Sanitary Aid Association), was not a very numerous one. The Rev. H. Cooper occupied the chair, and introduced the lecturer, who proceeded to read a lecture on "Volunteer Sanitary Work—Auxiliary and Subordinate to that of Medical Officers of Health," prefacing her remarks with the observation that as the system she was about to advocate had been carried on successfully in the borough of Hastings for more than ten years, and as the distance between Eastbourne and Hastings was small, those present might easily investigate and judge for themselves whether or not such work might be organised beneficially throughout the kingdom. Mrs. Johnstone then went on to say that notwithstanding all the attention bestowed by medical officers of health on the prevention of scarlet fever, that fever continued to spread and increase from year to year. If, therefore, it could be shown that in any place this fever had been so controlled during ten consecutive years as that in no instance during that period had a serious or general epidemic occurred, then public attention might well be bestowed on the means taken to procure that result. In order to stop the spread of the disease, it was plainly necessary, first, that the system of disinfection practised should be complete in its results; and secondly, that this system should actually be applied. The lecturer then proceeded to relate the manner in which the association at Hastings carried out its work. The association, she said, was maintained purely by voluntary subscriptions. The parochial clergy having poor in their charge were nearly all on the committee, and all on the subscription list, and these, with their district visitors and the teachers of schools, formed the agency for information. By these, information as to the first outbreak of disease was brought to the notice of the association, and the association's visitor, who was the only salaried officer, and who was in receipt of 40*l.* a year, then visited the sick-house, instructing the parents or those in charge how best to treat the sick patient and prevent infection. The association was always more or less supplied with disinfectants by the public bodies of the town, and had always worked in union with the medical officer of health and the medical men in the town. She strongly urged that the subject of treating sick people should take a place in the compulsory code of education for women, and in conclusion advised that public bodies should take into their employ a woman teacher, to perform similar duties to those undertaken by the visitor of the Hastings Association, as well as a sanitary inspector.

The lecturer at the conclusion was loudly applauded, and on the motion of Professor Robert Kerr, seconded by Mr. Councillor Hamilton (Brighton), a vote of thanks was accorded to her.

The Duration of Life.—Why is it Shortened?

The above was the subject of the lecture delivered on Monday evening, to a crowded audience, by Dr. Alfred Carpenter. The chair, in the absence of Dr. Jefferys, was occupied by Mr. G. A. Wallis. Dr. Carpenter, in commencing his lecture, said he thought it spoke well for Eastbourne that they should dare to hold such an exhibition as had been opened that day. At any rate, it showed the honesty of purpose that guided the men of Eastbourne so far as sanitary matters were concerned. They had every reason to be satisfied with their sanitary condition, because if they could show a death-rate of only thirteen in the thousand they had a pre-eminence which was held by no other town in the kingdom. People, however, died at Eastbourne as at any other place, and among them young children. We were told in Holy Writ that the days of men were threescore years and ten, and in bygone days men lived to a great age. Now, however, the average life of persons was forty-one years, and he contended that it was in consequence of our disobeying the laws of nature that life was so short in this age. There was no reason why we should become the subjects of disease except for one fact, namely, that we do that which we ought not to do. No one ought to die of disease, and he fully believed that a time would come when none would die except from old age, which was the natural form of death. Pure water and good sanitary arrangements, he was convinced, would do this in the end, and no one could deny that the operation of local authorities was capable of reducing the death-rate. To prove this, he quoted statistics of certain towns to show that since proper control had been exercised by public bodies appointed under the Public Health Act, the death-rate had greatly decreased. Continuing, he said we were told "That the sins of the father shall be visited upon his children to the third and fourth generation," and stated that he fully be-

lieved that hereditary diseases would not extend beyond the third or fourth generation if the laws of Nature were only properly attended to. If this were attended to he was certain that hereditary diseases would be got rid of. Turning to zymotic diseases, he showed that these were brought about by uncleanliness and by reason of the pores of the skin being stopped up and the excreta kept in the body instead of being thrown off. As evidencing the good effect of properly carrying out sanitary laws, he alluded to the low death-rate in prisons and barracks, which, a few years ago, were the most unhealthy dwellings in the country, but which now were filled with the latest sanitary appliances. Turning to the effects of alcohol, he said the deaths produced by alcohol in this country were something enormous. It was not drunkenness that caused the deaths, because hundreds of thousands of people were killed by alcohol who had never been drunk in their lives. The consumption of alcohol hardened certain carbon matters in the blood, and prevented the proper escape of carbonic acid gas from the body, and he had no hesitation in saying that life was shortened by the consumption of alcohol. He spoke of the necessity of phosphates in food, and said he was glad to see that a call was now being made for bread from which the phosphate and fibrine had not been taken by the miller. After a passing allusion to the danger of defective drainage, a subject, which would be dealt with more fully by subsequent lecturers, the speaker said that the day was close at hand when persons letting houses with foul drains, from which injury resulted to those who lived in them would be punished. In conclusion, he said he was certain that the people of Eastbourne were determined that no seat of disease should find an entry into their town, and thanked the audience for the patient manner in which they had listened to his lecture.

THE BRITISH ARCHÆOLOGICAL ASSOCIATION AT MALVERN.

The thirty-eighth annual congress of this Association was opened on Monday last in the hall of the College at Great Malvern.

Lieut.-General Sir John Hawkins, R.E., in the name of the town of Malvern, and as chairman of the Local Board, bade the Association welcome, and the Vicar, the Rev. Prebendary Gregory Smith, as chairman of the Local Committee, added a few well-chosen words.

The President of the Association, the Very Rev. Lord Alwyne Compton, Dean of Worcester, having expressed his thanks on behalf of the British Archæological Association, then proceeded with his address. He observed that the last occasion of the kind at which he had taken the chair was at Northampton, as president of the sister Society, the Archæological Institute, and on that occasion he chose as the subject of his address "The Defence of Restoration." He went on to say that, much as they must sympathise with the anti-restoration movement, there was not a little to be said on the other side. They were so accustomed to the well-ordered beauty of their churches now, that they forgot the terrible disappointments of their earlier days. They had in Worcestershire side by side a restored and an unrestored church,—at Pershore. One, indeed, was a splendid example of Gothic, the other a very poor one, and so, it might be said, the comparison was hardly fair. But still he would ask any of the younger members of the Association, who could not date back their antiquarian pursuits to the earlier half of the present century, when they visited Pershore, after inspecting the abbey church, to go also into the other parish church close to it, and to believe that many a parish church which they now viewed with artistic pleasure, if not with antiquarian interest, was but little better, say in 1840, than that which seemed now so strange. They could not forget that these churches were buildings intended for a most important and sacred use, and to sacrifice the very purpose of their erection in an attempt to preserve their ancient features would be something like the action condemned by the ancient poet of those who, for the sake of life, would lose all that made life valuable. If churches were now less interesting as monuments, they were much more beautiful, more suited to the purposes of devotion as churches. Not that there was any reason why both objects should not be attained to. It was usually from ignorance or carelessness,—it might be of the architect, it might be of the builder, or of the restoration committee,—that the old and interesting features had disappeared when the work of restoration had been carried out. If care was taken to preserve, as far as possible, all old work, restoring when necessary, and not otherwise, just so much as needed it and no more, and not attempting, by over-careful matching of stone, and other like tricks, to deceive the future student,—however much the ignorant sightseer might be taken in,—he believed that the antiquary and the devout Christian might be equally well satisfied. This course, he added, might be advantageously followed in cases other than those of churches. Referring to the well-known Queen Eleanor Cross at Northampton, which had been restored three times, as an illustration of his view, the very rev. president went on to refer to Worcester Cathedral, which he considered one of the finest examples of restoration to be met with: had he said of over-restoration he should perhaps have been misunderstood. He could not agree with those who would probably condemn everything that had been done. He thought the interior one of the finest that he was acquainted with,—the very finest, considering its size,—it must be far finer now than it was before the work was begun. The outside, no doubt, looked terribly new, but in an archæological point of view, what had been lost? The whole of the outside stone had largely perished in the beginning of the eighteenth century, from the ravages of the weather upon its surface. Mouldings and other delicate features could scarce be traced. Then came the hand,—not of the restorer, but of the men who wished to make it neat, and new, and tidy. They pared down the mouldering lines, and reduced each string-course to what they looked upon as a more perfect condition; they put on the top of pinnacle neat spire, formed like that of the neighbouring church of St. Andrew; they repaired the tracery of the east window according to their notions of what we should now call Late Gothic. Was all this worth keeping? Was it not far better that the east window, of which they saw so much from the interior, the pinnacle outside, the deep mouldings, and string-courses, should be renewed to something like their original Early English character, even if this involved some newness of appearance for a few years? The walls were dangerous,—unsightly modern buttresses supported them; nothing short of rebuilding would suffice. The internal stonework was replaced, stone by stone, as far as possible. He thought that, so far, the restoration of Worcester Cathedral was wisely and well carried out; but, in some respects, he thought it went too far. The large severe lancet windows had in some cases been subdivided by a mullion, and their heads filled by tracery of a later period of Gothic art. These features were removed at the restoration, and he regretted it, as they were part of the history of the building in the period of our greatest architects, and also because it seemed to him they had lost some beauty by the change. The Gulston Hall they must all regret; but they could not fairly blame the Dean and Chapter, who offered to find 5,000*l.*, one-half of the estimated expenses needed for the Gulston Hall, if those who desired its preservation would raise the rest; but they received only one promise of 5*l.* towards it. After some further remarks on the restoration of Worcester Cathedral, the president went on to ask if we, in our day, had any architecture at all. If what we built now lasted 500 years, would there be anything in it to tell in what century it was built? He had already said that the want of originality in these days might be partly the effect, perhaps also partly the cause, of our treatment of ancient buildings. Careful and minute study of old work seemed likely at least to check any freshness of artistic thought. It was quite true that in the period of the Renaissance the artists and architects did most carefully study and copy the work of the Romans as they found them in ruined amphitheatres and temples, and also in the domestic decorations of Herculaneum and Pompeii. But they were using them for new purposes. The palaces and churches of modern Italy were necessarily quite different from the houses and temples of the Romans, and thus what were then new elements of beauty were worked into architectural designs of which the essential constructional features, the plans, the elevations, the window spaces, the roof were already in full use, and from this combination of the old and the new a very beautiful style was soon produced, but the extraordinarily rapid deterioration of this style seemed to show that from the very first it was not based on sound principles. The copying of the ancient forms and ancient decorations seemed to have had not immediately but ultimately the effect of destroying style altogether, and now we have again taken to this copying, and he feared the result would be even worse than before. He feared they could not boast of a Victorian age of English architecture. As to any remedy, he feared there was none. In concluding his address, the President apologised for dwelling so much on the subject of modern architecture. If they were asked what was the use of the study of archæology, he answered that it was the handmaid of history; that it helped to fill up the outlines given us by the chroniclers of old times; and that by its means they might eventually hope to solve the great question of the unity or the non-unity of the human race,—of the original condition of man in respect of what, for shortness, we expressed by the words civilisation and morality.

Thanks having been voted by acclamation to the President, at the instance of the vicar, Mr. Wright, F.S.A., as congress secretary, gave an outline of the daily proceedings of the congress, and the party, under the guidance of Mr. Nevinson and Mr. Tyrrell, the hon. local secretaries, proceeded to the Priory Church, where Mr. W. Jeffrey Hopkins, F.R.I.B.A., and Mr. E. P. Loftus Brock, F.S.A., gave some account of its history and architectural features.

Mr. Hopkins said the priory was founded at the end of the eleventh century,—Leland said in 1085,—but prior to the Conquest a congregation of hermits resided here, and in ascending the hill joining the present priory is a place called the Hermitage. Aldwyne, the first prior of Malvern, was contemporary with St. Wulstan (founder of Worcester Cathedral) and the priory continued in a flourishing condition until the dissolution of the monasteries by Henry VIII. Mr. Hopkins proceeded to give reasons for his belief, judging from the remains of the old priory which had been excavated, that the church originally had an apse, and speculated as to the cause of the adoption of the double apsidal arrangement, which he thought might be attributed to a difference in the ritual of Continental and English churches. He considered that the double apse originated at Tours. The remains of the lady-chapel, he said, were all of too late a character to have belonged to Aldwyne's time, but they found them on the site where one should have stood. These remains convince him that the chapel formerly standing at the east end was either an aspidal or a circular chapel. Having glanced at what the presbytery of the original Norman church probably was like, Mr. Hopkins proceeded to describe the other portions of the building, taking for his guide such remains of the original building as still remained above or underneath the ground. As to the interior of the nave, instead of the walls presenting their present bare and cold appearance, the original would certainly have been covered with frescoes or distemper paintings. These were even introduced into our smaller parish churches of that date. The church, according to Mr. Hopkins's view, founded on the "faithful stones" that remained, answered in every particular to the description of a Benedictine church. Between the time of the erection of the Norman church and the partial rebuilding that took place in the fifteenth century, Mr. Hopkins said there must have been erected in connection with the church a very beautiful structure of the Decorated period, to which was to be attributed the admirable examples of detail which they saw built into the east end wall, which were dug up during the excavations made by the Rev. Mr. Dyson on the site where the lady-chapel stood. In some of the bosses which formed part of the roof of this chapel were still to be seen traces of gilding. Of the conventual buildings, with the exception of the fifteenth-century abbey gateway, he feared not a vestige remained except a few details of the old refectory. They knew, however, that the cloisters were on the south side, as at Worcester. Turning attention next to the Perpendicular work, he thought there could be no doubt that it belonged to the same date as the fifteenth-century work of Abbot Seabrook, of Gloucester, commenced in 1450. Prior John of Malvern commenced his about the same time. The manner in which the Perpendicular clearstory had been added to the old Norman work was

not satisfactory, and did not harmonise at all with it. Referring afterwards to the old painted glass in the windows, he considered there was none existing to excel it. Let them compare those windows with the dead, dull, heavy productions of modern times. Nevertheless, they had been shamefully treated, and their fragments jumbled together, owing to which many interesting subjects could not be made out. If he were asked what should be done with this old glass, his reply would be, "Simply nothing." He thought, however, that many of the subjects might be recovered and brought together. He would have correct tracings made of the windows, or drawings of full size, and then, following the lines of the leading, would have the drawings cut up into pieces, as one would for a child's dissecting map, and then using the pieces in the same manner, they might bring once more into juxtaposition the dispersed pieces, and recover many of the lost subjects. Referring to the more modern history of the building, Mr. Hopkins said that at the Reformation this monastery was doomed, like the others, to destruction, which the earnest pleadings of Latimer himself were unable to avert. He petitioned that it might, with a few others, be saved, and used for educational purposes, but in vain. The history of the church, from the Dissolution down to living memory, had been little else than the recital of acts of desecration, wanton folly, ignorance, and neglect. It had been restored in modern times and at different dates to its present state.

Afterwards a large number of members and visitors dined together at the Imperial Hotel, Lord Alwyne Compton in the chair.

We shall return to the proceedings of the Congress next week.

PROPOSED VESTRY HALL, ST. GEORGE'S, HANOVER SQUARE.

At a meeting of the St. George's Vestry, on the 18th inst., Mr. Finch moved that the Vestry invite the competition of twelve architects to submit plans of a Classical character, for the construction of vestry-hall and offices in Mount-street, and that three premiums be offered of 100*l.*, 50*l.*, and 25*l.* respectively, for the first, second, and third best plans. That the Vestry appoint a committee, to be called the building committee, to prepare a plan of the exact site for new buildings, and the necessary conditions upon which the competition is to be invited. The extreme limit of the cost of the building, exclusive of the fittings, to be 12,000*l.* The price for the land (3*l.* per superficial foot) had been agreed to. He thought 12,000*l.* would be a sufficient sum for the building. Mr. Dowdeswell seconded. Finally the Vestry decided to adjourn the question till the first meeting in November.

THE "AUBEL" PRINTING PROCESS.

The "Aubel" system of reproducing architectural and other drawings has been the subject of some interesting remarks in one of the German technical journals. The process differs from photo-lithography and other systems of a similar character, inasmuch as neither asphalte nor gelatine is used in the plates. The secret of the invention consists in the composition of the photographic plate, from which an impression is obtained either on a lithographic stone (whence the printing is done as usual), or on bright-polished zinc plates. The latter are, by an etching process, made to serve for the printing-press in such a manner as to replace the ordinary wood-block. An unlimited number of copies of equal distinctness can thus be produced. The "Aubel" system surpasses ordinary photographic productions as to the size of the impression. A plan of Cologne is said to have been executed by this process, of the dimensions of 39 in. by 52 in., the whole printed in one piece.

RESTORATION OF THE CASTLE AT HEIDELBERG.

The attention of the Grand Ducal Court of Baden has lately been directed to the question of restoring the above noble ruins. A consultation of architects of note will, it is said, be shortly held to consider what steps should be taken. The subject has for some time been before the profession in Germany, and has attracted the attention of some of its most eminent members.

PRINCIPAL PORTAL OF THE EX-CONVENT OF SAN PABLO, VALLADOLID.

If we except Henry VII.'s Chapel at Westminster, and Roslin Chapel, Scotland, we have no examples of the elaborate surface richness displayed in some other countries in the buildings erected just before the Renaissance. Spain, as we have before had occasion to show, in the series of illustrations by which we are seeking to make better known to untravelled English readers than has hitherto been the case the architectural glories of that remarkable country, has many specimens of this extravagant style of ornamentation, belonging chiefly to the reign of Ferdinand and Isabella, A.D. 1474–1516, though some are earlier. We add to the instances of lavish exuberance we have already illustrated, a view of the principal entrance to the Ex-Convent of San Pablo, in Valladolid, completed in 1463, every inch of which is elaborately and beautifully carved, displaying groups of figures, pinnacles, foliage, and diapers in wild but not inharmonious profusion.

German influence is strikingly obvious in the design, and it has been attributed to a German architect. Mr. G. E. Street ("Some Account of Gothic Architecture in Spain") thinks it may possibly be the work of the artists Gil de Siloe or Diego de la Cruz, who wrought under Juan de Colonia and his son at the monuments and Retablo in the Convent at Miraflores.

DERWENT HALL, DERBYSHIRE.

Derwent Hall is a somewhat extensive shooting-box of the Duke of Norfolk, E.M., situate about thirteen miles from Sheffield, in the fertile valley of Derwent Dale, and surrounded by the Derbyshire moors. Originally the property of the Balguys, it passed into the hands of the Newdigates, from whom it was purchased by the present noble proprietor, who decided to pull down the later additions, which were of a farm-house character, and to increase the buildings in style with the genuine old work. The present buildings include the entrance-hall, with the duke's study on the left, all beyond this being domestic quarters, and on the right, beginning at the front, the duchess's boudoir, the library, dining-room, and drawing-room, of which we have already given an internal view, the sacristies, and the domestic chapel, a simple but massive building in the Early English style. The domestic quarters contain kitchen, scullery, housekeeper's room, still-room, butler's pantry, servants' hall, pantry, larder, dairy, game larder, gamekeepers' rooms, &c. On the two upper floors are thirty rooms for bed and dressing, &c. The stables contain fifteen loose boxes and stalls, a treble coach-house, 28 ft. by 18 ft., two harness-rooms, stablemen's mess-room, and three bed-rooms. The stables are fitted up by the St. Pancras Iron Co. in a simple but substantial manner, the woodwork for stalls and loose boxes being of teak, and the walls lined with the Farnley Co.'s buff and brown glazed bricks. All the sitting and bed rooms are lined with panelled wainscot oak, principally carried out by Messrs. Dealy & Horner, of Sheffield, but the drawing room and dining-room, which are carved, are by Messrs. Farmer & Brindley. The doors are furnished with simple iron handles, finger-plates, and hinges, treated by Professor Barff's process, and harmonise well with the solid-looking oak. These fittings, together with the stained glass of the chapel, were supplied by Messrs. Hardman & Co., of Birmingham. Dog-grates are used throughout the house, the fire-places being lined with tiles of different designs.

The walls are composed of the local hard stone, which is speedily assuming the grey tints of the old work, and thereby will soon render the building all in unison. The roofs are covered with the old-fashioned grey slates, and this further helps to carry out the Duke's wish to keep up the character of the works throughout.

The whole of the works have been carried out under the supervision of the architects, Messrs. Joseph A. Hansom & Son (now represented by Mr. Joseph Stanislaus Hansom, F.R.I.B.A.), of 27, Alfred-place West, South Kensington; Mr. James Firth is the clerk of works. The Hall is situated so far from most of the depôts of material that the later works have had to be carried out without a contract. Messrs. Robert Dennett & Co. were, however, the contractors for the chapel and part of the house. Later the labour has been obtained by the clerk of works, and goods have been supplied by separate tradesmen, amongst whom in addition to those already referred to, we may mention Mr. Corrie, of Sheffield, plumber; Messrs. Edmundson, of Westminster, electric bells; Messrs. S. C. & J. L. Ellis, of Sheffield, hot water apparatus; Mr. Chadwick, of Sheffield, plasterer; Messrs. Minton & Hollins, tiles; Messrs. Stuart & Smith, dog-grates and tiles; Messrs. Longden, of Sheffield, kitchen fittings; Messrs. Chew & Sons, of Stroud, iron casements.

NEW BOARD SCHOOLS, ROCHDALE.

The Rochdale School Board, in January last advertised for competition drawings for the erection of new schools to accommodate 500 children, and the appeal was responded to by about thirty-eight architects. The committee, after consideration, selected the design with the motto "Utility," by Messrs. Mangnall & Littlewoods, architects, Manchester, who were instructed to procure estimates and carry the work out. The contract has been let to Messrs. Peters & Sons, builders, Rochdale, and the amount will be under 5,000*l.*, including fittings and architects' commission. We give view and plan.

The mixed school for boys and girls is situated at the south end of the site in Derby-street, and is 60 ft. in length by 20 ft. in width, and 20 ft. in height, and accommodates 120 scholars, allowing 10 ft. of floor space for each scholar. Directly communicating with the school-room are four class-rooms, two of which will accommodate fifty-five, and the other two thirty-five scholars each, allowing 10 ft. of floor space for each scholar.

Hat and cloak rooms and lavatories are provided for each sex in immediate connexion with the entrances.

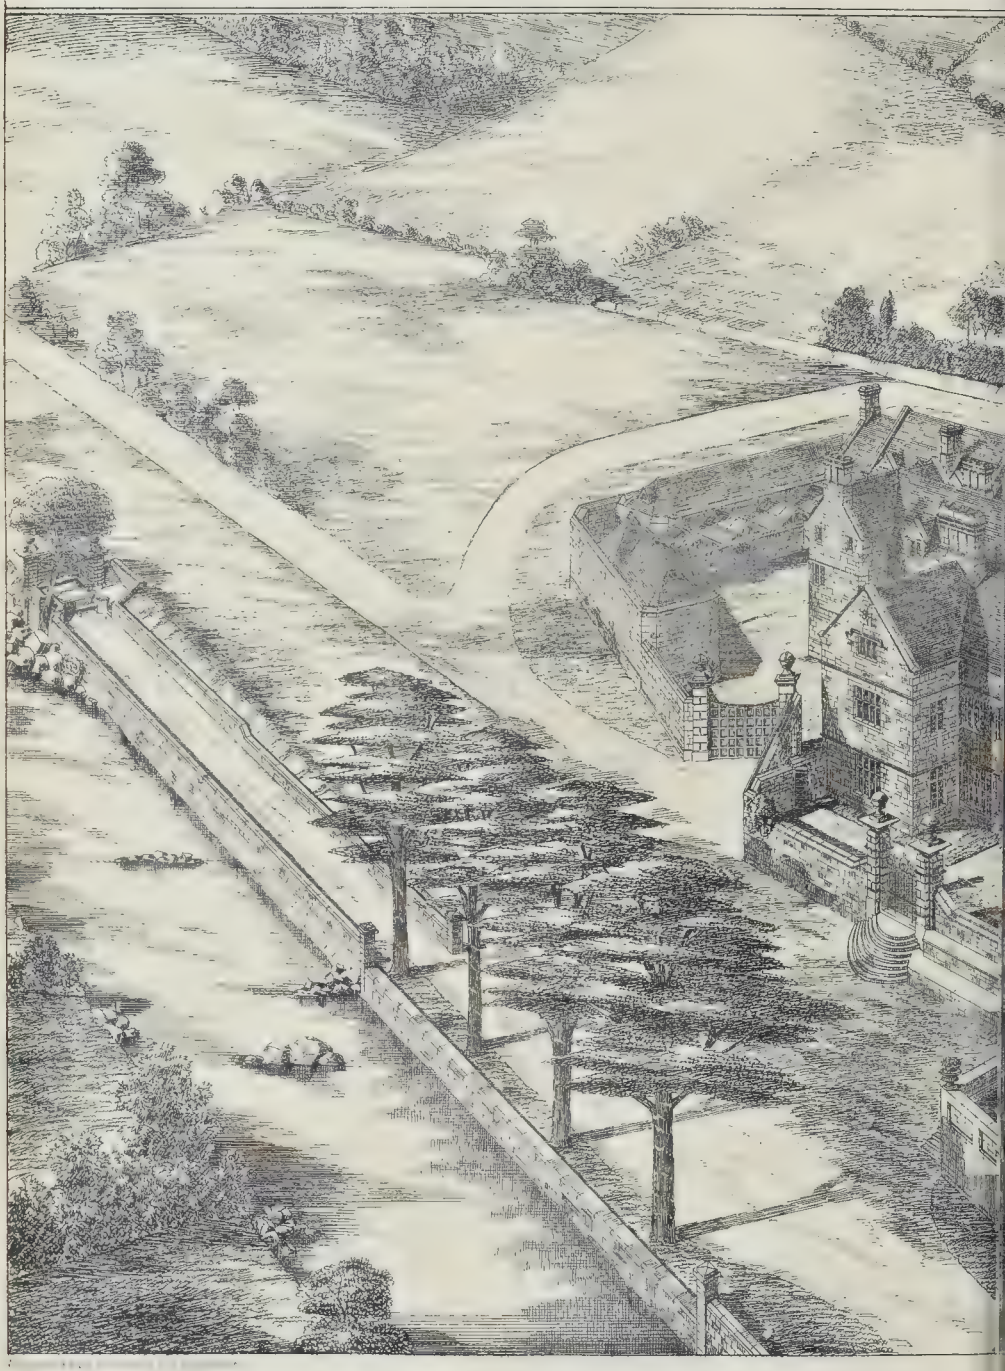
The infants' school is situated at the north end of the site in Derby-street, the principal approach being from this end. The school is 48 ft. in length, by 20 ft. in width, and 20 ft. in height, accommodating 120 children allowing 8 ft. of floor space for each. Two class-rooms each accommodating forty children, communicate directly with the school-room. A white glazed brick dado, 4 ft. high, will go round each school-room and class-room, which will have a pale green tinted band of another colour at the top and bottom. The ceilings to each school will be splayed on each side. The roof principals being exposed to view, are in pitch-pine, varnished.

The boys' and girls' latrines are situated adjoining to the west boundary wall, and will be on the dry-earth closet system, properly ventilated. The infants' latrines are situated near to the back school-entrance, and are approached by a covered passage.

The schools and class-rooms are to be heated by hot-water pipes.

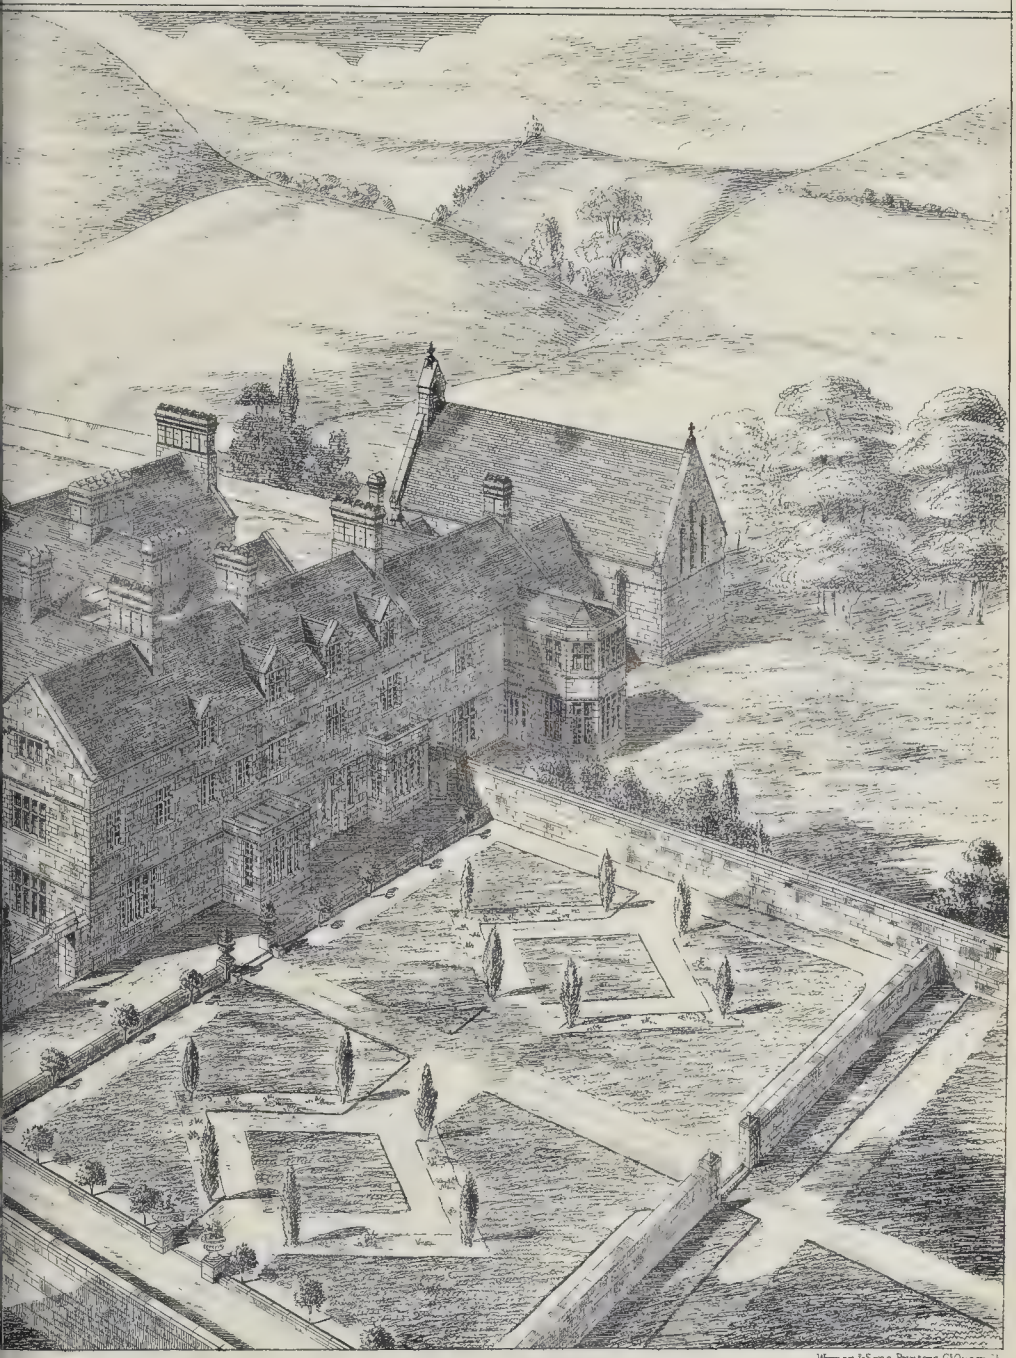
A louvred ventilating-shaft is fixed on the roof over each school, and communicates with openings in the ceiling regulated by doors which open and close with pulley and cord. Fresh air is introduced every few feet along the walls of each school, at a height of about 7 ft. above the floor, by means of Sherringham's ventilators, and foul air is to be let out at the ceiling level through Boyle's tale ventilators.

The windows are also adapted for the free admission of fresh air by the simple plan of hanging the top part to fall inwardly (regulated by cord and pulley), and the lower parts, being sashes, afford means of cleaning.



The elevations are faced with stock bricks, with masonry sparingly introduced where most required to throw off the water, namely, to stringcourses and sills and the upper part of cornices; the rest of the ornamental work will be executed in red terra-cotta.

The roofs will be covered with green Welsh slates fixed to yellow pine sawn battens. The ridges are of red Staffordshire crested tiles.



The internal joiner's work, such as doors, &c., is to be of pitch pine, varnished.

Mr. John Churchill, who, in company with a companion, had been accidentally drowned a few days previously at Sidmouth, Devon, was buried there on the 17th inst. Several hundreds of his fellow-workmen and friends followed him to the grave. Mr. Churchill was only twenty-eight years of age at the time of the lamentable occurrence. He was out-door foreman to Mr. Harry Hems, of Exeter, having succeeded, in that position, the late Mr. Stephen Shute, whose death was referred to in the *Builder* for September 18, 1880.

EDUCATION AND EYE-SIGHT.

The reports of the third examination in technical education, held by the City and Guilds of London Institute, show a considerable increase in the number of students. In 1879 the number was 202; in 1880, 816; in 1881, 1563. The successful candidates were respectively 151, 515, and 895; and the localities or centres of examination were 23, 85, 115. The towns furnishing the greatest number of successful candidates were Bolton, Manchester, Newcastle-on-Tyne, Huddersfield, Oldham, Crewe, and Gateshead.

Of the 1563 candidates for a pass in the present year, only 213 took up more than a single subject of them, 126 were examined in mechanical engineering and some one other subject; 43 in flax and cloth manufacture, and 16 in fuel and iron and steel. The subjects named show the thoroughly useful objects of the Institute. About 770*l.* will be distributed this year to teachers, and 240*l.* in money prizes, besides thirty-eight silver and forty bronze medals. Among the subjects in which examination will be held in 1882 are breadmaking, distilling, linen-bleaching, linen manufacture, jute manufacture, electric lighting, electrical instrument making, metal plate work, and weaving and pattern designing. Flax will not be treated as a separate subject. It is, however, one on which in the present year the answers of the candidates have been pronounced by the examiners to be generally unsatisfactory. A winter-class of lectures, including laboratory and workshop instruction, will be given at the temporary classroom of the Institute, in Cowper-street, Finsbury. They will include the subjects of fuel and illuminating agents, distilling, metals and metallic compounds, electric lighting, transmission of power, electrical instrument making, and electrical laboratory apparatus. There will also be evening trade classes in bricklaying, metal platework, masonry, carpentry and joinery, sanitary engineering, house decoration, and modelling. In contrasting this broad scheme of useful education with the merely literary standards of the Board schools, it may be well to call the attention of the examiners to the eyesight of the pupils. How far this may be affected by the evening classes is a question of no slight importance to the future welfare of the students. The inquiry is suggested to us by the fact that the very journals which announce the programme of the City and Guilds of London Institute happen to contain an extract from a German paper showing the immense deterioration of the eyesight of the children in Germany, which is attributed in great measure to the small crabbed print of the school books, printed in the German character. Myopia prevails among these unfortunately over-educated little mortals, in exact proportion to the advance of their studies. Over an average of 10,000 children, from five to 11 per cent. in the elementary classes proved to be shortsighted. In the next grade of schools for girls the proportion rose to from 10 to 24 per cent. In the *Realschulen* it is from 20 to 40 per cent.; in the Gymnasia from 30 to 55; and in the two highest classes of all, between 35 and 88 per cent. Out of 600 students of theology at Tübingen 79 per cent. suffer from myopia. The question may occur how far an excessive use of tobacco has produced a hereditary weakness of vision, but the real practical value of that learning which is acquired at the cost of eyesight is to our view extremely problematical.

THE MOSAICS IN THE CATHEDRAL AT AIX-LA-CHAPELLE.

Early last month the mosaic decorations in the cupola at Aix-la-Chapelle were completed. The subject represented is that of the "Court of Heaven" as described in the Book of Revelation, with the twenty-four elders offering homage. The work partakes somewhat of the nature of a restoration, for it is on record that such mosaics once existed and were destroyed.

As soon as the work was decided on, Baron Bethune, of Ghent (according to the details before us), undertook to furnish the designs, in which it was intended to follow as closely as possible the outlines given by historians of the original mosaics. The changes made are only in points of detail, such as the omission of the seats of the elders,—which, as their owners were represented standing, must in their emptiness have produced an ungraceful and monotonous effect in the original work. The execution of the designs was entrusted to Dr. Salviati, of Venice, about whom our readers have often heard.

Professional and general opinions seem agreed as to the success of this work, in which simplicity of design united with brilliancy of colour produces a striking effect. From the octangular construction of the dome, and the fact of the light being thrown upwards from the eight windows, the effect is heightened in a singularly effective manner. The comparative rapidity with which the work has been executed speaks well for the suitability of Salviati's process for modern requirements; and when we consider that the space covered is 3,000 square feet, the time occupied seems relatively short. The whole has been done within two years, we note, although the time allowed by contract was three years. This rapidity is only attainable by the conjunction of material, financial, and technical facilities of the highest grade. In the different processes of manufacture there are, it is said, the most recent improvements; but the chief advantage of the system is in a process described at some length in the notice before us.

The ancient method of fixing mosaic work was to cover the wall under treatment with a coating of cement, and insert the pieces separately. This system (still in operation at Rome) only allows two or three workmen to be engaged at any one time, if due regard be given to regularity of effect. The Salviati process consists in the distribution of various parts of the design amongst different workmen at the factory. Each part of the design is pasted on paper, the reverse of the blocks being outwards, and thus when being placed in position it is only necessary to bring the separate sheets and fix them into the cement. The removal of the paper from the face of the blocks is, we presume, easily accomplished. Apart from the advantage of rapid execution, it is remarked that the uniformity and regularity of surface (so necessary in mosaic work) are much more easily attained by this method than when each block has to be fixed separately. Of course, the saving of labour allows of a proportionate reduction in the cost of the new system as compared with that of the old.

There remains, however, the question of durability to be glanced at, and under this head, we notice that although some of Salviati's mosaics have been twenty years in position, they are as firm as when first executed, although in some cases exposed to unfavourable climatic and atmospheric influences. The testimony of the late Sir Gilbert Scott is cited in the remarks before us in support of this assertion, with respect to work executed under his direction, such as the Wolsey Chapel at Windsor, the Albert Memorial, &c.

It is suggested that the remaining portions of the octagon should be decorated in a similar manner. Its present undecorated state is to be changed, and the effect produced by the mosaics overhead leaves no option to the chapter but to make the rest of the Emperor Karl's chapel in harmony with the dome. According to the *Echo der Gegenwart*, "Germany has been enriched by a noble work which meets not only the religious but also the artistic requirements of such a task. Aix-la-Chapelle thus offers a new inducement to art-loving strangers to pay the city a visit."

NEW BRIDGE AT SAGAN.

The relative advantages of wooden and stone bridges as to cost of erection and of maintenance form the subject of a statement in a foreign contemporary. The town of Sagan, in Silesia, is now erecting, at a cost of about 10,000*l.*, a sandstone bridge with five arches of sixteen yards and a half each in span, the roadway being nine yards and a half across. The life of a massive bridge is estimated at 300 years, and the cost of maintenance is reckoned at a quarter per cent. per annum, the renewal of pavement forming the bulk of this charge.

The wooden bridge now being replaced was erected in 1849 at a cost of 2,000*l.*; repairs during the thirty years have cost 2,500*l.* From experience it has been found that about thirty years is the average duration of a wooden bridge; hence in a century, the process of building would have to be repeated twice more. The total expense would have to be counted as nearly 15,000*l.*

SUSSEX ARCHÆOLOGICAL SOCIETY.

This Society had its excursion the other day to Ashburnham, and the proceedings of the day were very successful, although the weather was not altogether propitious. The gathering-place was at Pevensey, whither the members with their friends flocked from all parts. A large number assembled, to be further reinforced at Ashburnham, where about 350 persons mustered in front of the church. The arrangements for the excursion had been made by a sub-committee consisting of the honorary secretaries, Rev. W. Powell, of Newick, and Mr. F. Barchard, of Horsted Place, and Mr. Robert Crosskey, Mr. J. C. Lucas, and Mr. Griffith. The train reached Pevensey at about eleven o'clock. The visitors repaired first to Westham Church, in the vicinity of the station,—a plain but rather interesting old church,—over which the party were conducted by the vicar, who proved a most amiable *cicerone*. The church, which is a large stone structure, built partly in the Decorated style, dates back to the year 1539. It consists of a chancel, nave, and two chapels, that on the south being dedicated to St. Katherine. From Westham the party proceeded to the fine ruins of Pevensey Castle, which is one of the most perfect of castellated remains of Roman origin. The outer walls of the castle inclose an area of about eight acres, and are almost 20 ft. in height. In the interior is a smaller fortification of a quadrangular form, with round towers, and which was once entered by a drawbridge. The circumference of the outer walls is about 260 rods, and they must at one time have been of immense strength. A few of the party, who had made good use of their time, went on to Pevensey Church, a fine and interesting structure of considerably greater age than Westham, and which was much admired. According to the programme, the Rev. Mr. Powell was to have read a paper on this church, but, as is too frequently the case on such occasions, the programme had to be curtailed for want of time. The party then took to the carriages, and soon left the quaint old town behind them, crossing that flat marsh country,—there pronounced "the Mash,"—towards Ashburnham. After about half an hour's drive, revealing some interesting sights in the distance, such as Hurstmonceux Castle, one of the oldest brick buildings in the county, the seemingly small, but scattered, village of Wartling was reached, and a halt was made to inspect the little church, which lies far away from the main portion of the village, in one corner of the parish, somethiog like five miles from the opposite end. The Rev. Dr. May, acting as *locum tenens* for the Vicar, was awaiting the arrival of the party to explain the principal features of the church. A well-preserved Catherine-wheel window, and a Pelham buckle of more than the ordinary size in the outer wall, are worthy of notice here. The wooden spire is rather a rarity in Sussex. The ride from Wartling to Ashburnham, leading through pleasant lanes and fine woodland scenery, was very enjoyable. There was Hurstmonceux Castle to be seen, and Windmill Hill, the seat of Mr. Curteis, and as the ridge of high land was crossed the openings in the green woods and plantations revealed some charming views. The Vicar (the Rev. Rose Fuller Whistler) was waiting outside the church at Ashburnham, and proceeded at once to show the visitors first round and then over the church, explaining its various features of interest. The church was rebuilt in 1663; and one of its features is that in all the windows the mullions are of oak instead of stone. The Vicar read a paper on the church, in the course of which he said: With the exception of the tower, the whole of the parish church of Ashburnham was rebuilt in 1663 by that well-known cavalier John Ashburnham. The church consists of a tower, a nave, and a chancel with two side chapels to its north and south. The nave is entered from the tower by seven steps, and from it there is a similar approach to the chancel. The effect of this arrangement is extremely striking, the sacrarium (altar) standing out in grand relief as you approach it from the west end of the building. A somewhat steep fall in the ground from east to west has thus been happily utilised, and if the construction is not unique, it has at least given an unusual character of grace and boldness to the building, with an effect of light and shade not often to be found when side aisles are wanting. This effect, however, is generally missed, as the entrance is usually made by the porch on the

COST OF SOME GASHOLDER TANKS.

The following particulars, showing dimensions and cost of a certain number of gasholder tanks, may be found useful. Fuller details of one of the tanks would be valuable. Messrs. Aird & Co. were the contractors:—

London Gasworks, Nine Elms.—Diameter of concrete tank, 200 ft.; depth, 45 ft.; cost, 17,600*l.*

Phœnix Gasworks, London. — Diameter of brick tank, 218 ft.; depth, 44 ft. 6 in.; cost, 21,446*l.*

Gas Light and Coke Company, London.—Brick tanks—diameter of brick tank, 195 ft.; depth, 37 ft. 6 in.; cost, 15,000*l.* There are six similar tanks. Cost of same, 90,000*l.*

Leicester Gas Tank.—Two of brick, each 172 ft. diameter, and 37 ft. deep. Cost of each, 15,200*l.*, or 30,400*l.* the two.

Birmingham.—Brick tank, diameter, 185 ft.; depth, 41 ft.; cost, 18,190*l.*

FROM ABROAD.

The exports of window-glass from Belgium during the first four months of this year were 29,884,003 kilos., against 31,961,587 kilos. in the corresponding period of last year. Business with England, the United States, and China, shows a decrease, as well as the exports to Hamburg and the north of Europe generally. On the other hand, an increase is reported in the trade with Holland, Russia, Spain, Italy, Turkey, Roumania, Chili, and Peru.

A curious fact is noticed in the German press, which is not without interest to the building industry. At a small village on the Baltic, noted for its quietness, Prince Frederick Charles has had three block-houses erected for himself and his attendants. They are constructed of whitewood, the furniture being of the same material, and were made in Sweden. The ease with which the different parts are arranged to be joined makes this sort of house, it is remarked, particularly serviceable for temporary habitations on the seashore, or in mountain districts.

An institution for the higher technical education of those engaged in textile industry was recently founded at Crefeld. The erection of a suitable building has just been commenced, and will occupy two years. The city has given a site, and contributed 7,500*l.* towards the cost of erection. The plans are by the municipal architect, Herr Burkard, to whom the direction of the works has been entrusted, under the official supervision of the Government authorities at Düsseldorf.

THE NEW WOOL EXCHANGE BUILDINGS.

A large block of new buildings, connected with the recently-erected Wool Exchange, has just been completed in Basinghall-street, extending from that thoroughfare into Coleman-street. The site upon which the buildings have been erected is that known as Sambrook-court, which contained a number of old offices, all of which were cleared away. The Basinghall-street frontage is in the Renaissance style. The elevation is 72 ft. in height, a turret being carried to a height of 80 ft. above the ground level. The elevation, which is about 60 ft. in width, is faced on the ground-floor with Aberdeen polished granite, eight massive columns of this material supporting the upper portion of the frontage, which is in Bath stone, carved and decorated. The frontage has a range of five bay-windows to each floor. The main cornice at the top of the building is surmounted by a balustrade, and behind this is a Mansard roof, with dormer windows, and the cupola bell-tower, in which it is intended to fix a clock, and also, it is stated, a peal of bells. A special feature in the carving is that heads of several members of the present Cabinet, including the Prime Minister, Lord Kimberley, Sir W. V. Harcourt, and Mr. Chamberlain, are represented in the *façade*. Amongst other similar heads are those of the Lord Mayor, Mr. Hughes, of the Wool Brokers' Association, and Mr. Faithful, of the Merchant Taylors' Company. Other portions of the carving are symbolical of the Seasons, Agriculture, and Foreign Continents. The chief entrance to the building is in the centre of the Basinghall-street frontage, between the granite columns already referred to. There are four massive wrought-iron gates at the entrance, of elaborate design and workmanship. One pair at the carriage entrance from Basinghall-street, is 10 ft. in height and 6 ft. in width, whilst the other pair, giving access to the various offices in the buildings, is 6 ft. in height and 4 ft. in width. The fittings throughout the buildings of the large number of offices for tenants, are complete and costly. All the offices are warmed by Doulton's porcelain slow combustion stoves. In the basement, extending from Basinghall-street to Coleman-street, under the entire block of buildings, including the Wool Exchange itself, is an unusually large room containing an area of 10,000 ft., suitable for storage purposes, and which is easily capable of sub-division. There is a goods entrance to this apartment in White Horse-yard. The whole of the premises, from Basinghall-street to Coleman-street, including the Wool Exchange and the section of offices completed about twelve months ago, together with the buildings just finished, which complete the whole, occupy a ground area of about three-quarters of an acre.

The architect of the several buildings is Mr. John Gordon, under whose superintendence the whole has been carried out, Mr. J. Sim having acted as clerk of the works.

ARCHITECTS' CHARGES.

PARAIRE *v.* THE ALCAZAR COMPANY.

The following is a copy of the Referee's award in this case, particulars of which were given in our last:*—"In the High Court of Justice, Queen's Bench Division, between E. Lewis Paraire, plaintiff, and The Alcazar Company (Limited), defendants—Whereas by an order of Master Gordon made in this action, and dated 13th June, 1881, it was ordered that the following question arising in this action, namely, the matters of account herein, be referred for inquiry-report to me, Jno. Whichcord, or to such person as agreed upon by the parties, or in case of difference to be named by the Master. And whereas, by another order made in this action by Master Dodgson, dated 5th July, 1881 and made by consent of the parties, and upon reading the said order of 13th June, 1881, and upon the defendant company admitting their liability to the plaintiff except as to the amount due to him, and withdrawing the first paragraph of their statement of defence in the said action, it was ordered that the matters of account in this action directed to be referred for inquiry and report by the said order be referred for inquiry and report to me, the said John Whichcord, of Palace-chambers, Westminster, late President of the Royal Institute of British Architects, under Section 56 of the Judicature Act, 1873. Now, I, the said John Whichcord, having taken upon myself the burthen of the said reference, and having heard the said parties by their counsel and their witnesses, and evidence produced before me, do hereby report to the Court as follows: that is to say, that I have considered the matters of account in question in this action, and I find that the total amount due to the plaintiff in respect of the matters aforesaid was at the commencement of this action 1,043*l.* and no more. As witness my hand this 12th August, 1881.

(Signed) John Whichcord,
Referee.

Witness,—E. Edward Habutt, Merchant,
31, Lombard-street."

AN AUTOMATIC COUPLING FOR ROLLING STOCK.

Messrs. E. Thomas and S. Cowdery, gentlemen connected with the Railway Department in Sydney, N.S.W., have just perfected a most important invention, which has for some time stood the test of actual work on the Darling Harbour Railway Lines. Messrs. Hudson Bros., the eminent engineering firm, of Sydney, who are always ready to undertake and to carry out any improvements connected with railways, have taken great interest in the invention, and on the 1st of July invited a number of gentlemen to witness the second and final public trial of the coupling. Among those who responded to the invitation were:—Sir Henry Parker, Sir John Robertson, his Worship the Mayor of Sydney, Mr. G. Cowdery, the engineer of existing lines; Mr. R. H. Barnett, the locomotive engineer; Mr. J. Trevor Jones, city engineer; Mr. J. Barcett, colonial architect; Mr. A. Mountain, city surveyor; Mr. J. Rae, Under-Secretary for Public Works; Mr. W. Read, traffic superintendent. The constructor of the new coupling fully explained the nature of the invention, and stated that five fatal accidents had recently occurred, which might have been avoided if this invention had been in use. The testing train consisted of engine and tender, three trucks, and a break van. The coupling consists of a tumbling hook and adjustable link, which is strong, and stands out horizontally, but is capable of moving upwards, when the inclined plane on the projecting end of the hook strikes its underside. The strength of the hooks was fully and satisfactorily tested by attaching to the train about thirty trucks, many of them laden; whilst in motion, the trucks having the new coupling attached were frequently and easily uncoupled, and the general opinion was that the experiment was in every way satisfactory. Mr. Hudson expressed his conviction, before the large assembly, that the new coupling would be soon generally adopted. Patents have been taken out for Europe and the colonies.

W. C. T.

* See p. 250, *ante*.

THE BRAKE QUESTION.

Sir,—I think that it is time that the deplorable accidents which have occurred through the use of defective brakes should be thoroughly brought before the notice, not only of the profession of engineers, but also before that of the public. I can unhesitatingly say that the use of such a brake as Mr. Eames's would have obviated so fatal an accident as that which occurred at Blackburn a short time ago.

Unfortunately in England everything is ruled by influence, that influence being what in the United States would be called the influence of the "Almighty dollar."

The enclosed extract from the *Manchester Evening News* of August 5th may have a peculiar interest:—

"An exciting scene occurred at Miles Platting Station last night, a man named Samuel Wolstenhulme, factory operative, Middleton Junction, as well as the stationmaster (Mr. Mayo), and the inspector (Mr. Clough), at Miles Platting, nearly losing their lives. It appears that Wolstenhulme had been across the double lines to the booking-office, and as the 6·30 Middleton train was entering the station, he ran in front of it for the purpose of getting on. Jumping on the high platform, he missed his footing, and fell on his head on the stonework, stunned, falling from there on to the line. The affair was witnessed by both the stationmaster and the inspector, who sprang to the stunned man's relief. Both seized hold of him at the same time, but both slipped, and all three fell on to the line. Fortunately, the occurrence had been seen by the driver of the train, and the brakes were applied. The three men had a marvellous escape, the train stopping a few feet only from them. Wolstenhulme was seriously injured by his fall."

It is somewhat amusing to me to have it asked in a certain journal "if Mr. Campin has heard of Westinghouse's brake"; but it is beneath my notice. Francis Campin.

Sir,—I have read with interest your remarks in recent numbers of the *Builder* on continuous brakes, and on the Blackburn accident, and hope you will allow one who, as a constant traveller, takes an interest in the continuous-brake question, to make a few remarks. I do not think you are quite warranted in thinking powerful (and trustworthy) continuous brakes liable to cause danger. I myself live on the Brighton Railway, about 1,400 of whose passenger stock are fitted with the Westinghouse brake, and have been a constant daily traveller for more than fifteen months, and all this time, though very quick stops are made, I have never once overshot the platform. From the evidence, the Blackburn accident seems to have arisen from the driver's not applying the brake in time, and not by its failure to act. He was not accustomed to drive the Manchester express, and was not quite acquainted with the brake's action! He had evidently heard the brake was very powerful, and thought its stopping powers were unlimited, and so thought he could stop a train running down a steep incline at over forty miles an hour in thirty yards from a block on the line.* The sad result was not the brake's fault. I am afraid it is very likely his statement as to the failure of the brake was an excuse for his ignorant rashness.

The best continuous brake should not be used at all to stop at termini or important junctions, and this is forbidden by most railways. That it is never so used on the Brighton I can witness; the brake is applied some distance from the terminus, and the train runs in at a moderate speed, and with ample space to be stopped by

* Precisely the evil to which our article points.—Ed.

the hand brakes. As I said, however, the Westinghouse never fails, when applied in time, *i.e.*, at 100 yards at thirty miles an hour, and a proportionately longer distance at greater speed. In Friday's *Times* it is stated a train fitted like the Manchester express was stopped in a space of 231 yards at forty miles an hour down a gradient of 1 in 82. This is a very short distance, and shows that the express driver must have been off his head when he attempted to stop at that speed in thirty yards. However, we shall doubtless have the matter made clearer when the Board of Trade report is published.

H. C. S.

CONDITION OF FAREHAM.

Sir,—Your correspondent, "Quæstor," has evidently found a "mare's nest" here. Fareham was one of the first places in England to adopt the Public Health Act, 1848, whilst far from being one of the worst in point of necessity; and it has had for over the last twenty years a most valuable system of drainage, water-supply, paving, lighting, streets and roads improvements, &c., in operation, equal in these respects to any other town of its size, and adopted and carried out before other towns of much greater magnitude.

The system of sewerage is known to the Local Government Board Inspector. It is the "Filtration" system, the solids being retained in tanks, removed periodically, and used as an agricultural manure. The effluent water, after filtration and deodorisation, passes out into the salt water, miles away from Portsmouth, and has no injurious effect whatever. There is not the slightest foundation for saying that the sewers are choked or the cellars flooded. In times of flood some exceptional difficulties have had occasionally to be overcome, but where is the place that has not difficulties at such times? Ours are exceedingly slight, and not to be mentioned in comparison. A flap-trap has been inserted in any case of back flooding, which is an effectual remedy.

With regard to the water supply, it is of the purest character, coming from the Portsdown Chalk Hills. The system is continuous during the day-time. It is turned off during the night to save waste.

The closing of one of the present churchyards and the provision of a cemetery is now the subject of correspondence between the upper and local Boards.

The sanitary rate has always been considered high here; it is now 3s. 8d. in the pound per annum, exclusive of poor-rates, water-rates, &c.

Fareham is mentioned in the directories, and is known to be one of the most agreeable and healthy towns in Hampshire; and, happily, no epidemic has occurred here for many years.

If "Quæstor" had applied to me, I could have given him any information; there would then have been no occasion for his troubling you.

Alfred Driver,
Clerk to the Local Board of Health.

"DAMP: A QUESTION."

Sir,—In building my house seventeen years ago, in Wimbledon Park, on gravel (not on clay), I took the following precautions against damp. Foundation on a yard of concrete up level with the excavation, two courses of slate above footings, land drain-pipe all round ditto, a dry area where the ground was against the house, 8 in. of concrete over the whole of the basement, with 2 in. of Portland cement for finish, a 9 in. cement skirting to ditto, no drains under the house. I mention all this to show I took great precautions against damp.

Well, the first three months after we got in the condensation was so great that the servants had a mop to remove it, and the tradespeople so dirtied the passages in consequence, that as a remedy the cook had a small quantity of mason's dust, and well payed the Portland cement over the surface. The condensation then ceased, and we have never had any trouble since.

H. F.

New Market for Liverpool.—At a meeting of the Liverpool Markets Committee, it was decided by seven votes to two to recommend the City Council to pull down the Theatre Royal and erect on its site a wholesale fish-market at a cost of 73,000*l*. The Theatre Royal, although said to be the best designed theatre in Liverpool, has latterly been altogether closed.

LIVERPOOL EXCHANGE STATION COMPETITION.

Sir,—Referring to my letter of last week to you, I will now attempt to perform my promise.

There is, sir, a wide difference in such competitions as this, and ordinary ones. Here was not a question of taste, on which we all may differ. The reason for this competition was to improve the existing disconfiture in *levels*, practicable inlets and outlets, &c.; and well we know that anything less than 1 in 30 must be out of the question for a 27 ft. rise on granite setts, yet nearly all competitors have got 1 in 15.

Did Sir John Hawkshaw desire to ignore existing facts, that such a gradient as 1 in 15 would not be sanctioned in such a case by any of his brother engineers?

I recently noticed an account in the *Citizen* of the new large buildings for Bishopsgate Goods Station (Great Eastern Railway), most important buildings, and there they have 1 in 27 for 17 ft. 5 in. rise.

Did Sir John overlook some of the designs by accident?

There appeared an able letter in *Engineering* of last week from Mr. Blackbourn, C E, who after, to my mind, satisfactorily proving that the three premiated designs should be out of court on account of levels, exits, and entrances, asks if there is no design sent in to fulfil the conditions? I can honestly reply to this in the affirmative, by pointing out a design I feel almost certain must have been lost sight of, the motto of which is "Direct." It has a cab inlet and outlet where required, viz., opposite Moorfields, and of a practical gradient of 1 in 20, with passengers' thoroughfares at each important approach; Fithebarn-street with shops and offices; emigrants' accommodation ample, and cut off from passengers.

Architectural detail was, I anticipate, outside the question altogether; but in this design the elevations were simple and honest, and I take simplicity and stability of work to be all that is required for a railway station. The greater consideration should be the best convenience to be obtained for the public. Is there in this country any modern built railway station having a gradient of 1 in 15 or a 27 ft. rise?

I am at a complete loss to see the grounds on which so able a man as Sir John Hawkshaw based his awards; it would be very satisfactory to know what they were. Surely the directors and shareholders will institute a more searching inquiry into these facts of levels, &c., for what I have stated are plain defects, and although I have particularised one special design, there may be others equally demanding attention.

I will say nothing about the three awards being made to three Manchester men, but it is certainly a coincidence.

A Non-Competitor.

P.S.—As Mr. Blackbourn truthfully points out, the Board of Trade requirement for raising a main country road macadamised with a rise of 18 ft., is a gradient of 1 in 20.

THE VERGERS OF YORK MINSTER.

The Very Rev. the Dean of York has written the following reply, we will not call it answer, to our correspondent "F. S. A.":—

I venture to think that it is scarcely fair that those who are filling responsible positions should be publicly assailed by anonymous correspondents in the newspapers, and I should be glad if the editors of all respectable papers would exclude such communications from their columns. As regards the vergers of York Minster, I can only say that I believe they are very anxious to perform their difficult and often delicate duties with courtesy and efficiency. I have from time to time received anonymous imputations concerning them, which I have treated with the contempt such communications deserve. The only complaint which I have received substantiated by names and dates I carefully inquired into, and found that the verger in question had simply and temperately carried out his orders, and that he had been very rudely treated. The visitors to York Minster comprise a large number of persons of various degrees of intelligence, and it must be very difficult to give information which shall be equally acceptable to persons of very different capacities and education. The anonymous correspondent of the *Builder* does not give us any clue as to his own mental capacity, or inform us what grade of information would have satisfied him; but I may say that, during my residence at York, many visitors to the Minster have afterwards been guests at the deanery; and many have gone from thence to the Minster and returned, and I have heard nothing from them but expressions of approval of the genial courtesy with which they have been treated by the vergers, and of the interesting information which has been imparted to them. If anybody, whether a resident in York or a stranger, has any complaint to make, I shall be at all times ready to hear it, to inquire carefully into it, and to give such redress as I feel that it deserves. At the same time, I feel myself bound to protect the vergers as long as they are doing their best to discharge the complex and difficult duties of their office from any frivolous, groundless, or cowardly complaints which may be made about them.

Arthur P. Purey Cust, Dean of York.

"THE ENGLISH LAND SYSTEM."

Sir,—The above is the heading of a letter appearing in your journal of the 6th instant [p. 192], signed "B. H. Thwaite," &c.

If you will allow me to make a few remarks upon your correspondent's suggestion (No. 1) in that letter, I shall feel obliged.

Mr. Thwaite suggests that there should be "such an alteration of the land laws as would make it possible for any farmer to become possessed of the land he cultivates in a certain number of years," &c. Such a consummation is possible even now, provided, of course, that the present owner of a farm thinks proper to sell it to his tenant.

Now, does Mr. Thwaite mean that he wishes a law made to compel the owner of a farm to sell it to his tenant "in a certain number of years," if the tenant desires it? If he means that, he is advocating a very dangerous doctrine, and one possibly that he might repudiate if he saw the working of it; for he may be sure that other interests besides that of the ownership of the land would come to be dealt with in the same manner when once such a course was commenced. Tenants and hirers of every description of property would want it to be made possible that, "in a certain number of years," they may become possessed of the ownership of the property they rented or hired, and, following the same principle through all the affairs of life, we should arrive at the very acme of confusion.

The views I have set forth are, of course, patent to yourself, sir, and your correspondent himself may, as much as I do, deprecate the full outcome of his suggestion, if it was ever made the law of the land.

I could remark upon other portions of Mr. Thwaite's letter, but it would trespass too much on your valuable space.

H. M.

LAND IN ENGLAND.

Sir,—It is very satisfactory to learn, on the authority of the President of the Board of Trade, in his speech at Ipswich, a few days ago, that "our principal industry is still the production of wheat," and the statement may serve as an antidote to the gloomy view expressed by your correspondent, "A Hampshire Man," in a recent issue [p. 93], who seems to think that, agriculturally at least, England is used up.

I am not one of those pessimists who have adopted that view, because I do not choose to ignore the fact that the succession of bad harvests we have experienced in England is, in the natural course of things, not likely to continue. The years of famine will assuredly be succeeded by years of plenty. What I fear most is that when the favourable seasons come, we shall not be in a position to take advantage of them. Our land is gone and is going clean out of cultivation. The complaint is in every county that agricultural land can neither be let nor sold. As a consequence, the income derived from land is, both to the owner and cultivator, either completely gone or has become very much reduced. To those limited owners who have only a life interest in their properties, and cannot therefore sell, and have no inducement or means to improve, and have besides in many cases heavy charges to meet for dowries and settlements, the position is very trying. This class of owner, which is much more numerous than is generally supposed, deserves our sympathy and assistance. I should propose to invest every present owner with a power of absolute disposal, and wherever there are settlements charged upon his land, he should have the option of disposing of the land provided he invested an equivalent in Consols or in Government annuities, either of which are certainly equal in security to the land itself. If he have an absolute power of disposal of his land, we may naturally expect in time to find that the younger children will get a share with the eldest, and if all land is compelled to have a registered title, we ought to have cheap and easy conveyance. With these changes and some fair average harvests, such, as I am thankful to say, we are likely to have this year in the Midlands, a desire to return to a country life and the cultivation of the soil will be a general feeling.

E. Grimes.

COCOA-NUT FIBRE MATS.

Sir,—A recent number of your paper contained a notice of the Furniture Trades Exhibition at the Agricultural Hall. I was in charge of Stand No. 1 of Messrs. Treloar & Sons, of Ludgate-hill, whose exhibits are noticed by your representative. The well-known high character and powerful influence possessed and exercised by the *Builder* induce me to ask respectfully the favour of space for a word of explanation, that I would gladly have given to your representative had an opportunity presented itself.

In your notice it is stated that "the first stand, for example, exhibits Messrs. Treloar's mats, some of which are in process of manufacture. They are excellent things of their class, as every one knows; but in those in which variety of colour and some slight ornamental treatment are adopted, we cannot but be struck with the raw and disagreeable tones of the colouring; yet these are from a firm which largely deals in importing Eastern rugs and druggets. Surely their own imports ought to teach them more in regard to form and colour in work of this class."

I presume that the "Imperial" mats shown are here referred to; if so, their implied defects as regards variety of colour, ornamental treatment, and character of design, are easily explained. Cocoa-nut fibre is an intractable material in its natural state; but an unscrupulous use of dye stuffs, and even the process of bleaching, would greatly extend the scope for varieties in colour and design, and might even make it possible to imitate the colours and designs of Eastern rugs and druggets, but at the expense of the non-absorbent character, strength, and durability of the material, which by bleaching and dyeing is made soft, limp, and flabby. The agents used in the bleaching process are sulphuric acid and chloride of tin. Dr. Letheby and other eminent chemists have expressed their professional opinion that bleaching destroys the durability of the material.

The mats we are referring to are made entirely of cocoa-nut fibre, unbleached, and without the application of any dye stuff whatever. Such varieties in tone and design as are obtained,—the range is necessarily limited,—are by the use, in its natural state, of fibre imported from different tropical countries and islands, the brightest colour from Cochin China, the darkest from the Fiji Islands, and the middle tints from Ceylon and Japan.

It is hoped that as good use as is possible is made of these materials for slight ornamental treatment; if not, the goods are fairly open to adverse criticism.

J. Mould.

STAINED GLASS.

London.—A memorial window to the late Mr. Joseph Mills has been recently placed in the Church of St. Stephen, East India-road. The three lights contain the subject of "Our Saviour preaching from the Ship," with appropriate emblems in the tracery above. The work was executed by Mr. George Rees, of Lamb's Conduit-street.

Leire (Lutterworth).—Three Munich stained-glass windows, by Messrs. Mayer & Co., have lately been erected in the parish church of Leire, near Lutterworth. They represent figures of St. Peter, St. James, and St. John, and are in memory of various members of the Richardson family.

CHURCH-BUILDING NEWS.

Brighton.—The Church of the Annunciation, Brighton, was reopened on the 7th inst., after enlargement from plans prepared by Mr. Scott, of Regency-square, under whose supervision Messrs. Cheesman & Co., builders, have added to the church on the south side an aisle capable of providing accommodation for about 200 persons. A new choir-screen has also been erected.

Shipbourne.—On the 6th inst., the Archbishop of Canterbury consecrated the new parish church of Shipbourne, Kent, situate midway between Tonbridge and Wrotham. The church has been rebuilt at the cost of Mr. E. Caralet, of Fairlawn. The building is Early English in style, and has been erected from the designs of Messrs. Mann & Saunders, architects, Westminster. The plan of the building is cruciform, and a substantial tower rises over the intersection of the chancel, nave, and transepts. The material used is Kentish ragstone (a considerable portion being taken from the old church), with Bath stone dressings. Internally there is a great deal of decorative work. At the east end is a reredos, made of pink alabaster, enclosing an *alto rilievo* of "The Last Supper," in white alabaster, which extends above the communion-table. The east window is in three lights, between which run slender shafts of green marble. The lights of the window display "The Crucifixion" in the centre, with the figures of Mary and St. John on either side; and underneath each of the three principal designs is a lesser subject. The walls of the chancel, on which "The Lord's Prayer" and "The Decalogue" are placed, are decorated. This portion of the interior is the work of Messrs. Mayer & Co., of Munich and London, who have also provided the other windows of the church, which are all likewise of stained glass. The building of the church has been carried out by Mr. Allcorn, of Shipbourne, under the superintendence of the architects, who, it is mentioned, were assisted in the drawings by Mr. Pearsall. Mr. Andrews acted as clerk of works. The whole of the woodwork, including the fine roof of the nave, is of oak, and accommodation is provided for about 250 people. The masonry work was undertaken by Mr. Hughes, of Maidstone. The pavements, which throughout are of marble mosaic, were laid by Messrs. Burke & Co.; and Gregory's patent wood-block floor has been laid under the seats. *Sgraffito* decoration in the Early English style adorns the walls of the nave. The execution of this was entrusted to Messrs. Trollope; and carved ornamentation both in wood and stone has been effectively wrought in various parts of the building by Mr. Bromfield. The lighting of the church has been provided for by Messrs. Edmundson, by means of atmospheric gas; and the fittings are the work of Messrs. Richardson, Ellson, & Co., who have also supplied the lectern. A "Gurney" stove is used for warming purposes. The total sum expended amounts to about 15,000*l.* The organ, which cost 800*l.*, was the gift of Mrs. Marshall, and the clock-tower that of Mr. Thomson Hankey. The church, which stands on high ground in a beautiful district, replaces one rebuilt by Lord Barnard, at his own charge, in 1722.

Melksham.—The parish church of Melksham was re-opened on the 11th inst. after the completion of sundry improvements to the interior and the erection of a new organ. The alterations to the structure principally affect the chancel, and they have been executed by Messrs. Wall & Hunt, of Brimscombe, near Stroud, under the direction of Mr. Street, R.A. An entirely new ceiling of panelled oak has been provided for the chancel, and the walls of the chancel and chancel arches have been thoroughly cleaned. This latter work led to the discovery of some interesting work in the shape of portions of a Norman arcade running along a part of the north and south sides, with one pillar in the north-east angle. The entire cost of the alterations in the chancel has been borne by the lay rector (Lady Awdry) and the vicar of the parish (the Rev. Prebendary Warre). The new organ, which has been placed in what serves for the north transept, is the result of a fund commenced by the Rev. Dr. Wilkinson when he had charge of the parish, and which has since accumulated to 770*l.* The organ was built by the Messrs. Conacher, of Huddersfield.

Pulford.—On the 11th inst. the Duke of Westminster laid the foundation-stone of a new church at Pulford. The new building is being erected on the site of the old church, which has been recently pulled down. The latter had been some time in a dilapidated state, and the Rector (the Rev. J. R. Williams) having represented to his Grace on several occasions the condition of the church, the Duke, about last Christmas, signified his intention of causing a new church to be built. The work is expected to cost about 5,000*l.* The erection of the building is in the hands of Mr. J. Douglas, architect, of Chester, and Mr. Parker, builder, Eccleston.

Weeley, Essex.—The new church of this parish was consecrated on the 9th inst. It has been erected from the designs of Mr. E. C. Robins, by Messrs. Saunders & Son, at the cost of about 3,000*l.* The church consists of a nave and chancel, 80 ft. long, including walls, and 40 ft. wide, including the north aisle, which is 50 ft. long by 13 ft. wide internally, and is separated from the nave by an open arcade of three bays, sustained on stone octagonal piers, with moulded caps and bases. An organ-chamber is provided between the vestry and the chancel, opening to the chancel by two arches sustained on coupled and attached octagonal piers, with delicately-moulded caps and bases. A vestry, 16 ft. by 12 ft. 6 in., is provided. The northern entrance-door has an internal lobby enclosure, and an external open-timbered porch, enriched with cusped tracery to the heads of openings and to verge boards. The roof is covered with the old tiles as far as they would go, leaving the nave and porch to be covered with new tiles. The timbers of the roof, nave, and chancel are boarded on the inside between the trusses, and are panelled with raised mouldings. The chancel takes the form of a pointed vault, and the nave a multangular form approximating to a semicircle, the whole being stained and varnished. The aisle roof is open-timbered, sustained on trusses at intervals. The internal height of the nave is 33 ft., and the external, 40 ft., the chancel roof being 6 ft. lower. The internal width of the nave is 24 ft., and that of the chancel, 19 ft. The pitch-pine varnished chancel choir stalls are raised three steps above the nave, and the Communion-table five steps. The reredos is draped with tapestry, and an elegant embroidered cloth covers the table. The pulpit is of pitch pine, with open panels filled with cusped tracery, moulded coping, and angular shafts and caps and body, all sustained on a plain stone plinth. A similarly-designed pillar lectern is on the other side of the chancel. The benches are of deal, stained and varnished, and very comfortable. The old font has been restored and refixed, and the remains of an old piscina, found built up in the walls of the old structure, have been converted into a credence-table. With the exception of the boarded floor of the vestry, the whole of the church has been paved with wood blocks, laid on concrete to a simple pattern, by Mr. Gregory, of Clapham Junction. The chancel tiles were executed by Simpson, of London. The design of the building has been in keeping with that of the tower, which gave the key-note, and which belongs to the Perpendicular period.

VARIORUM.

"The Forcing Garden, or How to Grow Early Fruits, Flowers, and Vegetables," by Samuel Wood (Crosby Lockwood & Co.), is a little book containing a considerable amount of information. It professes to give "plans and estimates showing the best and most economical way of building glass houses, pits, and frames for the various classes"; but these are given so rudely that they are of much less value than they might be. Mr. Wood should have taken an architect into council. It is all very well to say that "a good gardener should be the architect of all glass and plant houses," but a man may be a very good gardener, and even know what should be done, and yet not be able to set it forth so that workmen could carry it into execution, and this is apparently Mr. Wood's case. Still, his book will be found useful.——The *Gardeners' Chronicle* for the 27th, which gives a full report of the International Horticultural Exhibition at Manchester, includes a double-page coloured plate, from a painting by Fitch, representing a group of orchids. It is exceedingly well executed; the modulation of whites and delicate pinks is capitally managed, and the result is a very pretty plate.——The August number of *Our Own Country* gives us a paragraph as to Old Houses in Hull:—"In Silver-street is the old White Hart Inn, and at the High-street end of Scale-lane is another curious house with a projecting front. Formerly this was one of the chief inns of Hull, under the sign of the King's Head, and it has more than once entertained royalty. At that time it extended backwards about a courtyard, round which ran a gallery on the first floor, as was the fashion in ancient hostels. This, however, has been removed, but the staircase which led to it still remains. There is another old house at the south end of the street, believed to have been the residence of the De la Pole family, and now belonging to the Charterhouse. This is a charity for aged persons, founded in 1384 by Sir Michael de la Pole; but the present building (in Charterhouse-lane) dates from the later part of the eighteenth century. The master's house was built during the Commonwealth. It shelters eighty-six pensioners, 'brethren and sisters,' to each of whom a chamber with stipend and allowances is allotted. In High-street is another house of rather more interest architecturally, but chiefly noted as the birthplace of William Wilberforce. It is a brick building in what may be called the Dutch style, and must be of a rather earlier date than it looks, as Charles I. is said to have been entertained within it by Sir John Lister."——A few hints from Cassell's *Family Magazine* for August, as to "Fire Insurance Policies," may serve as a useful reminder to some of our readers,—"It must be borne in mind that, by the printed conditions of the policy, the insurance company undertakes only to guarantee the insured against loss. No matter for what amount the insurance may be effected, the company will not, in the event of a loss, pay more than what may have been the actual value, at the time of the fire, of the goods destroyed. For instance, the cost of a new building would not be paid should an old building or one wanting repair be destroyed, nor would a half-worn-out carpet or article of furniture be replaced by a new one. In effect, the company says, 'You may insure your goods for any amount you like, but should a fire happen, you must give us as detailed an account as possible of the articles destroyed or damaged, showing their values at the time of the fire.' For his own guidance, the insured should therefore keep at least a rough inventory of his effects, and revise it from time to time. It is a curious fact that, even with the most careful, the preparation of such an inventory generally shows household furniture in particular to be under-insured, the total value being almost invariably underestimated. While an insurance on household goods, clothing, &c., effected by the head of a family includes the property of all those members habitually residing with him, it would not protect the goods of a lodger or visitor, or of any member of the family not customarily residing under his roof. Nor does it insure any of his own property stored in any premises other than those mentioned in the policy; and therefore, in the event of such an ordinary occurrence as a change of residence, notice should be given to the insuring company of the expected time and places of removal, in order that the property may be held secured by them against loss by fire in either house. Should any member of the family, too, be visiting at a friend's, and a fire happen there, the insurance would not cover the clothing and property while away from the place mentioned in the policy. All these contingencies can, however, be provided for by special insurances."——Mr. Edward Walford, in undertaking to revive the *Sacristy*, expresses his determination to make it, in the domain of Ecclesiology and Sacred Archæology in all its branches, as good of its kind as is the *Quarterly* or *Blackwood* in the class of subjects with which they deal. Church architecture is to be one of the chief matters treated of, and the new number now before us includes a communication on the original position of the high altar in Salisbury Cathedral, by Canon W. H. Jones, of Bradford-on-Avon; and an elaborate paper on the existence of a recognised model or type adopted in the erection of churches before the time of Constantine, by Mr. Geo. Gilbert Scott, M.A., both illustrated. It is but fair to mention that the *Sacristy* is a Roman Catholic organ.——The *Holiday Number of Belgravia* is full of bright, pleasant stories, with here and there a dash of mystery, or it would not belong to *Belgravia*.

An Anonymous Donor has presented the handsome sum of 3,000*l.* to the building fund of the Birmingham and Midland Institute.

Miscellanea.

Bold-street, Liverpool.—New premises for Messrs. Van Gruisen, music-sellers, have just been erected in this well-known thoroughfare. The *façade* is described as being in a free French Classic style, carried out in white Cefn stone from near Ruabon, North Wales, with pilasters and columns in polished Shap granite, with bands of dark grey Aberdeen granite and polished Chesterfield stone bases. The entrance, placed in the centre of the building, has recessed and splayed sides to the shop-front. The upper portion of the building is spanned by a large arch, having on each side of the springing life-sized figures of Euterpe and Thalia. The whole of the ornamental carving on the premises has been carried out in the endeavour to make it symbolical of the use of the building, there being violins, trumpets, panpipes, flutes, and a variety of musical instruments, both ancient and modern, in the panels of the pilasters, and on the main frieze of the building. The floors are connected together by means of a large hoist, supplied by Messrs. Bunnett, of London, which is found to be a great convenience for moving the pianos from floor to floor. The building covers an area of 450 square yards. The architects are Messrs. E. & H. Shelmerdine. Messrs. Bennett & Sons, of Victoria-street, have supplied the hot-water piping which is laid round each floor; Mr. Ludwig Oppenheimer, of Manchester, the mosaic tiling; Mr. Cassidy, of Westminster chambers, Dale-street, the grates and mantel-pieces; Messrs. J. Hands & Co., of Birmingham, and Mr. James Lee, of Great Charlotte-street, the lamps and gasfittings; and Mr. Abbott, of Lord-street, the wrought-iron grille and gates. The carving is by Messrs. Dodd, Williams, & Evans, of Liverpool; the masonry by Mr. William Wood; the show-cases and fittings by Mr. Chas. Christall; and the whole has been designed and superintended by Mr. Henry Shelmerdine.

Paperhanging on Damp Walls.—A mode of hanging paper on damp walls has been patented in Germany. Lining-paper, coated on one side with a solution of shellac in spirit of somewhat greater consistency than ordinary French polish, is hung with the side thus treated towards the damp wall. The paper-hanging is then proceeded with, in the usual way, with paste. Any other kind of resin easily soluble in spirit may be used in place of shellac. A layer of paper thus saturated with resin is said to be equally effectual in preventing the penetration of damp. It is not stated how long lining paper prepared in the manner described will adhere to a damp wall. As far as we are aware, French polish peels off moist surfaces, or is decomposed by damp. However, the suggestion with regard to the new process remains a matter for speculation, and experience alone will solve the question. For this reason, it is worth while, in our damp climate, to try the experiment.

Macfarlane's Castings.—We spoke incidentally in our last of the attention paid by Messrs. Macfarlane & Co., of Glasgow, to the provision of sightly public conveniences. It may be useful to mention that one section of their illustrated catalogue, "Sanitary Appliances," gives complete information on the subject. It may doubtless be obtained without difficulty by parish authorities and others concerned.

St. Pancras Schools.—Quarantine Wards. The Guardians of the parish of St. Pancras have instructed Mr. H. H. Bridgman, architect, to prepare drawings for quarantine wards for twenty children, in sections of five each, as sent down weekly from the workhouse. Each section sent down weekly will undergo three weeks' quarantine before entering the schools. The wards will be combined with a new entrance lodge.

An important Series of Excavations has been carried on of late at the spot where the capital of the Dacian kingdom and of the Roman province of Dacia once stood. The remains of a Mithras temple have been unearthed, together with several inscriptions bearing upon the Mithras cult, and a collection of Mithras sculpture.—*Athenæum.*

Growth of Eastbourne.—We are told that Mr. Thomas Verity, architect, is now at Eastbourne, with a view to the erection of some buildings which will be a great addition to this watering-place. A sum of money, amounting, we believe, to over 100,000*l.*, has been placed at his disposal by a syndicate of financiers.

Kirkstall.—The partial decoration of the parish church has been completed. The work is wholly mural, and mainly on the chancel walls, of which the decoration is on a diaper ground, interspersed with a few bands of relieving colour. Above a dossal hanging are entablatures of six figures, painted on a dead gold ground, but mainly in outline, slightly tinted. On the wall north and south of the east window are John the Baptist and St. Stephen; and the north and south chancel walls contain the figures of the Four Evangelists. Each figure is surmounted by a canopy. The work is by Messrs. Powell Brothers, of Leeds.

Architects in South America.—According to *Engineering*, the Government of the Argentine Republic has issued invitations for competitive designs for a palace for the legislative assemblies, to cost about 36,000*l.*; a Catholic cathedral, to cost 58,000*l.*; a Palais de Justice, 26,000*l.*; a Government building (Government offices?), 22,000*l.*; and an Hôtel de Ville, also to cost 22,000*l.* Each of these buildings is to stand upon a separate piece of ground, 328 ft. square, and be surrounded with streets about 70 ft. in width, so that they will be well seen from all sides.

Brentford Drainage Competition.—The Local Board, acting on the report of Captain Galton, R.E., to whom the sixteen plans submitted in competition were referred, have awarded the first premium to Messrs. Gotto & Beesley, of Westminster. The estimated cost of the selected scheme is 17,800*l.* It is proposed to deal with the sewage by chemical precipitation in tanks, to be constructed on land adjoining the Ealing sewage works.

Ventilation.—We hear that the "Imperial" self-acting exhaust ventilators (Weaver's patent), which have been recently taken up by the Sanitary Engineering and Ventilation Company, of Victoria-street, Westminster, are being applied to the Shoreditch Town-hall for the ventilation of the council chamber. The company's "Imperial" ventilating tubes are also being fitted there.

TENDERS

The Thames Conservators and the Avoidance of Pestilence.

THE Conservators of the River Thames, in their Report for the year 1880, have fully justified the wisdom of the advice which we ventured to give with reference to their mode of proceeding in face of the Metropolitan Board of Works. At the very time of the publication of their report, public opinion is beginning to make itself heard on the subject in a manner that will soon become unmistakable. The utter absurdity of administrative and legislative effort for the protection and restoration of our rivers being attempted while the chief river is daily polluted by the most important municipal body in the kingdom, without the slightest pretext of sanitary precaution, is really too humiliating. With what force can the Local Government Board call upon Reading or any smaller riverain towns to divert their sewage from the Thames, while the mighty and unclean flow of London is silently accepted and endured? Not that it is silently endured by any riverain inhabitants from London Bridge downward, but what are such petty protests compared to the dignity of the Metropolitan Board of Works,—a Board, too, flushed with its triumph over the more ancient but less adroit body, the Conservators of the River Thames?

The Conservators tell us in their report that they "deemed it advisable that an inquiry should be held under sections 20 and 21 of the Conservancy Act of 1870." When it was first publicly known that this opinion was entertained by the Conservators, we took occasion to give reasons for concluding that to demand such an inquiry was only to court defeat, and to defer indefinitely the purification of the river. To say nothing of the character of the bar,—not in the river, but wearing wigs and gowns,—and of the technical and business-like array brought together for the attack on and the defence of an intolerable nuisance, if the Conservators had been as well served as their opponents, it was certain that they were basing their acts on very slippery ground. It is a matter of evidence that the Conservators of the Thames have materially improved the channel of the river, and that such improvement is still in steady progress. It is matter of notoriety that the Metropolitan Board of Works are outraging the primary principles of sanitary reform, relying on a technical oversight in the Act of Parliament, for which, if we are not very much deceived, that very Act contains a remedy, if wisely applied. It was certain, from the tone of the correspondence which had preceded the appeal to the Board of Trade, that the Metropolitan Board would resort to any expedient which they thought calculated to nonsuit the Thames Conservators. Independently, then, of that diametric contradiction of scientific witnesses which might have been anticipated, the attempt to prove material obstructions in a constantly improving channel was one evidently attended with the utmost difficulty, and the most serious doubt. Had the Conservators taken their stand on principle, the case would have been altogether different. They might have said, "The position of the Metropolitan Board of Works is quite anomalous. It is easy to explain how it has become what it is. We admit that, however it came about, we are precluded from doing our duty with regard to it. We may strain at the gnat of any petty provincial sewage, we must swallow the camel of the London sewage. This is an injustice, an iniquity, and a danger, which Parliament never contemplated, and to Parliament we must look for a remedy. But, mean time, is it true that these polluters of the Thames are within the four corners of the Act of Parliament? We maintain that they are not. While allowing the Metropolitan Board (pending the completion of the arrangements for sewage utilisation, which came to nothing) to pump the sludge into the Thames, the Act still stipulated that they must keep the sewage poison out of the river above Bridge. This they do not. As to this there is ample evidence. While the abomination at Barking is greater than can be well described, the Thames through London is, year by year, becoming more and more polluted by the sewage brought up by the flood. There is not enough time during the ebb to pass the volume of filth into the river, and the consequence is to be traced to London Bridge, to Westminster Bridge, to Battersea Bridge. The very *raison d'être* of any exceptional privilege granted to the Metropolitan Board is negatived. The Board is absolutely without defence, except defence of the pettifogging order."

Had this tone been taken by the Thames Conservators they would have at once received the warm sympathy and the full support of all sanitary reformers. And of two things one must have followed. On an application to the Master of the Rolls, who had already done justice in similar cases, the Conservators would either have obtained an injunction or not. We are of opinion that, if their case had been put as it might have been put, they would have obtained one. Not peddling as to measurements of mud, more or less thick, here to-day and gone to-morrow, as to which evidence and counter-evidence were equally valueless,—if the Conservators had stood on the main points of public policy, general tenour of legislation, abominable nuisance, and failure on the part of the Metropolitan Board to perform their part of a bargain which they drove to its utmost letter of limit, we believe that the law is strong enough to protect the Londoners from nuisances involving a risk of pestilence.

Suppose it were not so. Suppose that we were wrong, and that the Court had decided that the Metropolitan Board were in a position so little contemplated by any writer on English law that they had a Parliamentary title to commit an intolerable nuisance. What then? Would it not have become apparent, on the very face of the proceedings, that a case of oversight existed which it was incumbent on Parliament to rectify?

In a word, instead of seeking to prove what they could not prove, the permanent condition of a constantly shifting river bed, had the Conservators taken our advice, they would have had the public with them, they would probably have had the Court with them, and, if not, they would ultimately have had Parliament with them. But they took the other course, and now it is *da capo*, with the disadvantage of having been both beaten and ridiculed. Are we misstating the case? What do the Conservators now say? "It should be noticed that the question of the pollution of the river could not be raised in this inquiry under the sections of the Act of 1870." Did we not say so in the first instance? Was it not courting defeat to say nothing of the true question, the main question, the question which was no question at all, but a palpable, malodorous, pestilential fact, and to special-plead about obstructions which were in doubt, and which were only discovered as a kind of flank attack on the main position of defence?

Is it to be wondered at, then, if, not only "during hot weather, when there has been little rainfall," but at other odd times, "complaints of the pollution of the river within and below the Metropolitan district frequently reach the Conservators?" "The pollution thus complained of," the report naïvely admits, "is indicated by the offensive odour and highly discoloured state of the water." Although the discharge from Kingston, Richmond, and other places "may in some degree affect the purity of the river near the metropolis, the Conservators think it can hardly be doubted that the chief cause of the polluted state of the river within and below the metropolis arises from the discharge at the outfalls and storm outlets of the Metropolitan Board of Works."

It is unfortunate that even in this plain statement of a fact with which any impartial person must agree, the Conservators admit a qualification which we hold is not admissible; "in whose district," they go on to say, that is in the district of the Metropolitan Board of Works, "ordinary sewage is exempted from the provisions of the purification section in the Conservancy Acts." Is it so? That, of course, is the contention of the Board of Works. We do not

admit it, and certainly the Thames Conservators ought to be the last persons in the world to admit it. What is excepted from the jurisdiction of the Conservators is the discharge of crude sewage into the Thames at certain specified places, by the Metropolitan Board of Works, provided always that they keep the sewage out of the Thames within the metropolis. This they altogether fail to do. They may attempt to disprove that fact. It is for the Conservators to prove it, and the case of the Conservators is, not that ordinary sewage is exempted from the provisions of the Act, but that the special case allowed as exceptional in behalf of the Metropolitan Board (arising from known reasons) is not now existent. To pour sewage into the Thames in London is what the Metropolitan Board of Works has been prohibited from doing. It is what it now does. It is the duty of the Conservators to prevent them; and in a manly and straightforward attempt to discharge this plain duty, the Conservators may be assured of the sympathy and support of the public.

THE ARCHITECTURE OF MODERN ROME.

ON more than one occasion, in speaking of modern Rome, we have had, as our readers will doubtless remember, to refer with regret to the additions made to the Eternal City since it has ceased to be the City of the Popes and has become the capital of United Italy. The views we have expressed we find, if not exactly echoed, amply endorsed by so eminent a foreign artistic contemporary as *L'Art*, which in a recent issue, in devoting a short article to the subject of the architecture of modern Rome, does not neglect to wail bitterly over the degeneracy of the Roman architects, and their indifference to the great traditions of their classic and more modern ancestors. We, on our side, can fully endorse every sentiment uttered by our contemporary, and, indeed, to no one who may have recently visited the banks of the Tiber, and who may have known Rome in what may be called "the old days," can any expression of disappointment and regret come as a surprise. The *Times'* correspondent, in speaking recently of some important changes in Rome, not very unfitly referred to the mania possessed by the Roman authorities of treating their city much as Paris has been treated within the last generation, and still further following their model in the architecture adopted for the newly-built neighbourhoods. Paris, indeed, seems to serve as the sole model to the more actively employed Italian architects of the present day in their work of rebuilding and enlarging the old cities of the peninsula, which for so many centuries dictated the laws and standards of taste to the world.

From the very first moment of arrival in Rome the least observant stranger is forced to notice how apparently far is his ideal from that which he finds before his eyes. As he eagerly traverses the miles and miles of flat *campagna*, and finally finds himself landed at his journey's end, his illusions cannot fail to be cruelly shaken. If this effect is not caused by the railway terminus itself, a grandiose monument in the familiar Charing-cross, London Bridge, or Gare du Nord style, perched high on the classic summit of the Esquiline, it certainly cannot fail to be on the exit from the station, round which has grown up a huge new city of regularly laid-out streets, tall stone-built houses of the French boulevard type, to be met with in any of the great French cities. Later on the more artistically and classically disposed student may be to single out the still standing Baths of Diocletian and the tall cypresses, Michelangelo's cypresses of the Augustine cloister,—it is amidst the glare of brand-new houses and the stretch of a huge half-deserted piazza, threaded in several directions by tinkling tram-cars; the ruins once fixed serve, at least, to remind the stranger that he is in the City of the Cæsars. The impression of such a fact would, however, under other circumstances, be singularly shaken by the presence of so strikingly modern an edifice as the Ministry of Finances, or, as we should say, the Treasury buildings, not far from the railway station. Both features are, in an artistic sense, essentially commonplace, yet, it must be admitted, admirably serve the purposes for which they severally were intended. The Minister of Finances is lodged in a truly princely manner; his clerks are in scarcely less grandiose apartments; the corridors resemble the saloons of less magnificent edifices in other countries; but for the appreciative student in search of suggestive or pleasing effects, no memory will be borne away save that of pitiful wonder. Not far from this central feature of a new neighbourhood there is, we learn, to be built in a short time a huge art-exhibition palace, doubtless in a similar style to the Ministry of Finances, and new Rome, such as has risen within the last ten years round the railway station and the Esquiline, is rising in almost every quarter of the so long undisturbed city.

Our French contemporary has exactly touched the point when it remarks that the special character of the city which the modern Italians have improvised on the Esquiline is exactly that it possesses none. There is not in the whole new neighbourhood a single building, public or private, that can be said to be stamped with any Italian, still less Roman, peculiarity. The houses will doubtless furnish, as indeed they are intended to do, admirable lodging accommodation to suit the taste of the wealthy *bourgeois*, Italian and foreign, who have already invaded the neighbourhood; here, of course, no objection can be raised, though why all consideration of local needs, and especially of the climate,—so important and happily-seized a feature in the architectural work of the past in Italy,—should be markedly absent is a point which cannot fail to appeal to the observant eye. It is calculated to arouse surprise that not one of the Italian architects who directed the building of these houses should have given a proof of artistic inspiration. As our contemporary ironically remarks, it is not improbable that if there had been in any case any such desire, the authorities would at need have sternly repressed so untimely an intrusion or rather wandering of fancy. The sole edifices that attract the eye are the several Protestant churches which have been recently erected, and chiefly in the new quarters of the city.

Under such conditions, and this picture is applicable to the art of Italy from one end of the peninsula to the other, it is not difficult to foresee the near future of Italian art, unless some drastic measures, aided by a salutary reaction, are adopted to bring about a change.

THE STORY OF THE QUEEN'S PARK.

ONLY a few days have passed since the Park was gay with music and banners, and echoed to the shouts of a loyal multitude which had come to look upon their Queen and the tens of thousands of Scottish volunteers who marched before her in the pride of their patriotism.

In 1528, King James V. of Scotland commenced to build the palace of Holyrood. Maitland, in his "History of Edinburgh," following earlier records, tells us that the king enclosed a large quantity of ground in the neighbourhood of the palace "with a stone wall about three miles in circumference, which probably is nowhere to be paralleled; for, instead of trees and thickets for cover which other parks abound with, I could not after the strictest search discover a tree, in lieu whereof it is supplied with huge rocks and vast declivities which furnish the Edinburghers with the best of stones to pave their streets withal." A curious testimony to this statement, the existence of which was unknown to Maitland, is given in the Edinburgh Dean of Guild's Account Book for the year 1544, in which it is mentioned that the provost, bailies, and deacons of crafts, with a great part of the honest men of the burgh, consented to build at their own expense the whole of the breaches in the park wall that "circuit about Arthour Sett, Salisborie, and Duddingstone Crags, under protestation that their so doing prejudged not them concerning the causeway stones which they were accustomed to quarry from the said crags." In 1753, Maitland wrote, in continuation of the above statement, "I think it will not be amiss to observe that were they squared and sent to London, where they are in want of good stones to pave the footpaths or sides of the streets withal, they would turn to good account." In 1788 Arnot, in his "History of Edinburgh," writes,—"Of these stones considerable quantities are sent for paving the streets of London."

Arthur Seat, whether named from the probably mythic British king, or from the Gaelic title Ard-na-Said, the Place of Arrows, is the loftiest of the eminences once surrounded by the park wall, of which a considerable portion still exists as its eastern boundary; it is mentioned by Kennedy, a Scottish poet, who wrote previously to the close of the fifteenth century, "Arthur Sate, or ony higher hill." The oldest remains of bygone ages are to be seen on the face of the hill near Duddingstone, probably the work of agriculturalists in the age which followed that of the Crannoges and the Lake-dwellers. They take the form of a group of terraces, which consist of a flattish stripe, of varying breadth, from which rises a slope, at an easy inclination, to a similar stripe above, and so on to the highest of the series. It cannot be doubted that they are artificial, from the fact that they are in some cases sustained by a rude species of masonry. The late Dr. Robert Chambers, who inspected these and similar remains in other parts of Scotland, was of opinion that "there was but one reasonable solution respecting the origin of these terraces, and that is that they were designed for horticultural or agricultural operations at a time when the low grounds were either marshy or covered with forests." These terraces, wherever found, are styled by the country people "deases," or seats, a name which has also been bestowed on the line of crags to the east of the Hunter's Bog, which is now used as a rifle-practice ground. On a cone of the hill to the south of the "Lion's Head," as the top of Arthur Seat has been fancifully named, is a parallelogram of undressed boulder stones, which the late Mr. James Drummond, R.S.A., and secretary of the Royal Scottish Antiquarian Society, conjectured to have been the remains of a hunting-lodge erected when the Castle of Edinburgh and the town were one and the same, and the Forest of Drumselch, or Drumshench (the name is still attached to a portion of the western suburbs, and may be found in the Postal Directory of the city), covered the slopes of the Calton Hill and Arthur Seat. It was in this forest that David I. was miraculously rescued from the antlers of a furious stag by a cross which descended from the clouds, and his Majesty in gratitude erected the House of the Holy Rood, now known as Holyrood Abbey.

The only other remnant of antiquity enclosed in the park is the chapel of St. Antony, of which, with the exception of a portion of the northern wall, not one stone remains above another. No records exist to tell of its erection or when it was allowed to fall into decay. It was in good preservation at the commencement of the sixteenth century. In 1522, as we learn from the Edinburgh Dean of Guild's Account Book, 24s. 6d., Scots, were expended on the purchase of "three panels of glass for Saint Antony's windows, containing new glass 12 ft. and old glass 18 ft." Of the hermitage of St. Antony not a vestige now remains. The writer, in his boyhood, has often hidden from his companions in one of its cells, through which bubbled a spring of pure water. On the hill-side, immediately under the rock on which the ruined chapel stands, was a cairn of stones marking the locality of a murder in 1720. Nicol Mushet was a young man of some fortune, and had studied for the profession of a surgeon. For some time he led an irregular and dissipated life in Edinburgh. He was drawn into a marriage with a woman for whom he soon discovered he had neither affection nor respect, and he vainly tried by dishonourable means to obtain a divorce. At length the infatuated man borrowed a knife one day, hardly knowing what he wanted it for, and taking his wife with him towards nightfall, killed her at the spot once indicated by the cairn, which upwards of fifty years ago was removed to the gate leading into the old road to Portobello. Lockhart, in his "Life of Scott," speaking of the poet Crabbe's visit to Scotland, says, "But I shall ever regret that Crabbe did not see him (Scott) at Abbotsford, among his books, his trees, and his own good simple peasants. They had, I believe, but one quiet walk together, and it was to the ruins of St. Antony's Chapel and Mushet's Cairn, which the deep impression made on Crabbe by the 'Heart of Midlothian' had given him an earnest wish to see."

On the night of the 19th of September, 1745, Charles Edward encamped his troops on the side of Arthur's Seat, close to the village of Duddingstone (to this day may be seen some of the remains of the entrenchments), and on the following morning he marched to meet the army of Sir John Cope. The guns of Edinburgh Castle fired upon the little army, which soon got behind the shelter of the hill. Little more than thirty years later, Arthur's Seat was the scene of a strange military exhibition. The Seaforth Highlanders had been raised during the early part of the American war, under the idea, on their part, of not being obliged to serve out of

Europe. One morning, when at drill in the Leith Links, while in their ranks standing at ease, a clamour arose on the subject of their going abroad. Suddenly the whole body shouldered their firelocks, set off at quick march, and halted not till they gained the ridge of the hills, and fixed their head-quarters on the summit of Arthur's Seat, which they knew cavalry could not approach, and foot soldiers would not dare to attack. At length, Lords Dunmore and McDonald were deputed to enter into a parley with them, and matters were soon settled to the satisfaction of the mutineers. They had but one small favour to request, namely, "leave to shoot Finnie," the adjutant of the corps, which favour was politely declined.

Lord Mahon, in his "History of England," records that on the 17th of September, 1745, "Charles, till then at the head of his advancing troops, set forth to take possession of the palace of his ancestors. He entered the King's Park by a breach which had been made in the wall, and approached Holyrood House by the Duke's Walk, so termed because it had been the favourite resort of his grandfather, as Duke of York, during his residence in Scotland." The Duke's Walk, as it is still called by old people, and the level ground on either side, form the arena on which her Majesty has twice reviewed her Northern volunteers.

Of Salisbury Crags and St. Leonard's Hill there is but little to mention. On the latter, the Wizard of the North conjured up the cottage of David Deans and his two daughters, Effie and Jeanie, the shadow and the sunshine of his life. The footpath round the base of the Crags, formed early in last century to give work to the starving operatives of the city, and vulgarly termed the Radical-road, was a favourite resort of the inhabitants, as is shown by an extract from the *Gentleman's Magazine* of 1783:—"On the evening of the 26th of August, about seven o'clock, a considerable part of the rock called Salisbury Craigs fell down with a noise, which those who heard it at a distance mistook for thunder. Providentially from the badness of the weather, no person was within reach of the danger." This path, Sir Walter Scott writes, "used to be my favourite evening and morning resort when engaged with a favourite author or a new subject of study." The following is from the *Edinburgh Evening Courant* of October 29, 1728. "A person who frequents the King's Park having noticed a man to come from a cleft towards the north-west of Salisbury Rocks, had the curiosity some days ago to climb the precipice, if possible he might discover something that could invite him there. He found a shallow pit, which delivered him into a little snug room or vault hung with dressed leather, lighted from the roof, the window being covered with a bladder. It is thought to have been the cave of a hermit in ancient times, though now the hiding-place of a den of thieves."

THE CENSUS: POPULATION AND HOUSES.

THE Registrar-General prefaces his preliminary report on the Census of England and Wales by an almost disparaging remark touching the quantity and quality of the information contained in the document. Instead of apology, it challenges admiration of the industry and promptitude that must have been exercised to admit of the presentation, within such a short time as has been occupied in the task, of such a vast amount of digested, valuable, and interesting information. The books of the enumerators are under revision, and the result will appear with the detailed report, giving the ages, sexes, birth-places, occupations, civil condition, and other particulars regarding the people, and habitations occupied, unoccupied, and building, with much additional information connected with the numbering and classification of our population.

A highly interesting dissertation, historical and compendious, is given in the introduction, which is followed by a large number of tables containing suggestive information.

The first table gives the result of the enumerations of 1871 and 1881. According to last census, as compared with that of 1871, there were in England and Wales 4,833,844 inhabited houses, increase 574,727; uninhabited houses 380,684, increase 119,339; houses building 46,759, increase 8,956; population 25,968,286, increase 3 256 020; of these there were males 12,624 754, increase 1,565,820; and females 13,343,532, increase 1,690,200. The number of inhabited houses in 1801 was 1,575,923 against 4,833,844 in 1881; and the population 8,892,536, against 25,968,286. In the decennial period, 1801 to 1811, the rate of increase in the population was 14·30 per cent.; curiously, the rate from 1871 to 1881 is so near it as 14·34 per cent. From 1811 to 1821 the rate of increase was as high as 18·06 per cent.; and from 1851 to 1861 as low as 11·93 per cent.

Of the forty English counties, thirty-two show increased population, and eight counties a decrease. The aggregate decrease is 49,090. Cornwall is the most remarkable among the declining counties. The two divisions of the county, with 69,899 inhabited houses, show a falling off of 4,051 houses; the population, 329,484, has been reduced by as many as 32,859 persons since 1871. The census history of Rutland, the smallest county in England, is depressing. Like many other rural districts, it has no industries to absorb the natural increase in the population; it seems short of means, indeed, to maintain its inhabitants. The census of 1871 gave Oakham, the county town, 11,142 inhabitants, or 28 more than the population of 1861. In the census just taken its inhabitants are put at 10,978, or 164 fewer than it had in 1871. Uppingham, the only other town in the county, has 5,389 inhabitants, or 240 fewer than it had ten years ago. Two other sub-districts in the county, with 6,640 inhabitants between them, have a net increase of 26 in population. The decrease in the county is 639. It has 4,551 inhabited houses. The other counties that show a decrease are Cambridge, 1,431; Dorset, 4,795; Herefordshire, 4,328; Hunts., 4,094; Shropshire, 118; and Westmoreland, 826. Of the twelve counties in Wales, six have increased and six have decreased in population. The aggregate decrease in the six Welsh counties is 9,363, but the increase in the other six is 152,123, leaving a net gain of 142,760 for the Principality. Merthyr Tydfil, with 51,708, shows a falling off of 3,033, but other places in Glamorganshire show very large additions to their population, as, for instance, Pontypridd, with 93,479, shows an increase of 41,558 as compared with last census; Cardiff has 106,356 inhabitants, or 29,655 more than in 1871; Swansea has 95,068, an increase of 24,643. These three places have 49,786 inhabited houses, or 15,166 more than they had in 1871.

The increase in the population of some of the English counties is very remarkable. The population of Lancashire is 3,454,225, the increase being 634,730. The inhabited houses numbered 655,496, or 125,006 more than were enumerated in 1871. The houses building are 5,768, or 4,515 more than were in progress when last census was taken. The increase in Lancashire has been mainly in the south-eastern and south-western divisions of the county, that include Manchester, Salford, Liverpool, Warrington, Wigan, Bolton, Oldham, Ashton-under-Lyne, and a number of large manufacturing towns. The population of these two divisions of the county is 2,669,974; increase, 480,955. There are in the two divisions 503,411 inhabited houses, or 196,021 more than there were when the previous census was taken.

Liverpool and Manchester illustrate in a minor degree the tendency of population that London exhibits so notably, *i.e.*, to be attracted to important manufacturing and commercial centres, and to supply the day population of such places, but, when means permit, to find the home at some distance from such centres. The population of Liverpool proper is 210,161, being 28,250 fewer than in 1871; the inhabited houses, 31,678, are short by 2,615 of the number enumerated then. While this is so, however, there can be no doubt that the day population is fully sustained, if not increased, indeed, and the census tables leave no room for doubt as to where the Liverpool gentlemen find their homes. Toxteth Park, a suburb, has a population of 117,028, being an increase of 31,186 upon last census; it has 20,674 inhabited houses, or 6,519 more than it had ten years ago. It has also better play for the lungs than Liverpool. The seven districts in Liverpool that have sustained a loss of 28,250 inhabitants occupy an area of 2,470 statute acres, whereas Toxteth Park has 3,598 acres. West Derby, another suburb, has a population of 101,156, being an increase of 23,156; it has 18,885 inhabited houses,—an increase of 4,869; its area is 7,162 acres. Everton has a population of 109,788, the increase being 18,851; it has 19,120 inhabited houses, or 3,881 more than it had in 1871. In addition to these, there are many suburbs and places not far distant from Liverpool where the population and the number of inhabited houses have been very largely increased, such as Walton, Wavertree, Farnworth, St. Helen's, &c.

Manchester, also, is illustrating the tendency above referred to. In three of the districts of the city, Ancoats, Deansgate, and Market-street, there was a population of 89,674 at the last census, which was a reduction of 26,222 upon the enumeration of 1871; the inhabited houses, 17,442, were fewer by 3,750 than those enumerated in 1871. In Manchester proper, however, it should be stated, there is another large district, St. George, with a population of 59,131, being an increase of 1,039; inhabited houses, 11,994, an increase of 557. The three districts above referred to have an area of 1,148 statute acres. The Manchester men find homes in many of the pleasant localities that surround them, such as Choriton, Cheetham, Pendleton, Broughton, Didsbury, Altrincham, Bowden, Sale, Stretford, &c. In all the Superintendent Registrar's districts in which these places are embraced there has been a large increase in the population. Barton-upon-Irwell has a population of 72,825, increase 21,254; houses inhabited 14,344, increase 4,328; area 24,555 acres. Choriton has a population of 260,257, increase 48,873; inhabited houses 50,934, increase 9,454. Salford includes the pleasant residential districts of Broughton and Pendleton, the one has a population of 31,533, increase, 16,572; inhabited houses 6,162, increase 3,434. The other has a population of 48,409; increase 17,757; houses 9,525, increase 3,617. The two districts have an area of 4,711 statute acres.

Middlesex, with a population of 2,918,814, shows an increase of 379,049; inhabited houses 369,831, increase 48,602; uninhabited 30,592, increase 5,132; building 7,637, increase 3,228. It will be borne in mind in connexion with the above statement of population that London extends beyond Middlesex in various directions.

The Registrar-General treats London as consisting of a central area and beyond it a ring of districts, which is called the Inner Ring, and encloses "London Proper." "Greater London" is within a circle with a radius of twelve miles from Charing-cross, and embraces also parishes, any part of which is not more than fifteen miles in a straight line from Charing-cross. The population within the inner ring, or of London proper, was 2,803,989 in 1861; in 1871, it was 3,254,260; and in 1881, just enumerated, 3,814,571. The increase for 1881 is 560,311, as compared with the enumeration of 1871; and 1,010,582 as compared with that of 1861. The population within the Outer Ring, or of Greater London, is 4,764,312; being 878,671 in excess of that of 1871, and 1,541,592 in excess of that of 1861. The rate of decrease in the population in the Central area, including the City of London, is 7·8 per cent., according to the census of 1881. The rate of increase in the annular area, between the Central area and the Inner Ring, is 27·6 per cent.; over the whole of the area, within the Inner Ring, or London proper, the rate of increase is 17·2 per cent.; and within the Outer Ring, or Greater London, the rate of increase is 22·6 per cent., and has been 47·8 per cent. for the past twenty years. Greater London includes fifty-three parishes in Middlesex, thirty-five in Surrey, seventeen in Kent, 13 in Essex and ten in Hertfordshire. During the last ten years 6,388 houses in the Central area, previously used as dwellings, have been replaced by 3,045 houses that are only used for business purposes. The proportion of inhabitants of England and Wales who live within the Inner Ring or London proper, is one in 6·8. The average of persons to an inhabited house in England and Wales is 5·37, against 5·33 in 1871.

The areas, population, inhabited houses, and other particulars, are given in the census returns under a variety of groupings and divisions. They include abstracts of totals in enumerations from 1801 to 1881, with houses inhabited, uninhabited, and building; areas, houses, and population according to counties, and Parliamentary divisions of counties; to the Metropolis Local Management Act; to London School Board divisions; to London Police districts; Parliamentary boroughs; Urban Sanitary districts; Registration divisions; Superintendent Registrars' districts; and to Registration sub-districts. The table last mentioned gives more minute details than the others.

Referring to London, it appears that Kensington Superintendent Registrar's district embraces St. Mary, Paddington; St. John, Paddington; Kensington, and Brompton. It has an area of 3,441 statute acres; population

270,022, increase, as compared with enumeration of 1871, 52,910; inhabited houses 33,290, increase 5,708. Fulham, area 4,003 acres; population 114,811, increase 48,570; houses, 16,355, increase 9,163. Chelsea, area 796 acres; population 88,101, increase 17,363; houses 11,380, increase 6,395. St. George, Hanover-square, area 1,943 acres; population 149,603, decrease 6,684; houses 17,812, increase 731. Westminster, area 216 acres, population 46,456, decrease 4,725; houses 4,281, decrease 273. Marylebone, area 1,506 acres; population 155,004, decrease 4,250; houses 16,021, decrease 319. Hampstead, area 2,248 acres; population 45,436, increase 13,155; houses 5,869, increase 1,521. St. Pancras, area 2,672 acres; population 236,209, increase 14,744; houses 24,655, increase 552. Islington, area 3,107 acres; population 282,628, increase 68,850; houses 34,048, increase 16,969. Hackney, area 3,935 acres; population 186,400, increase 61,449; houses 27,503, increase 8,256. St. Giles, area 245 acres; population 45,257, decrease 8,299; houses 3,968, decrease 598. Strand, area 403 acres; population 33,514, decrease 7,825; houses 3,339, decrease 678. Holborn, area 816 acres; population 151,716, decrease 11,775; houses 15,184, decrease 1,271. London City, area 668 acres; population 51,306. decrease 24,677; houses, 6,548, decrease 2,867. Shoreditch, area 648 acres; population 126,565, decrease 599; houses 15,243, decrease 326. Bethnal-green, area 755 acres; population 127,006, increase 6,902; houses 16,663, increase 764. Whitechapel, area 378 acres; population 71,350, decrease 5,223; houses 7,602, decrease 670. St. George's-in-the-East, area 243 acres; population 47,011, decrease 1,041; houses 5,815, decrease 117. Stepney, area 462 acres; population 58,500, increase 810; houses 8,012, increase 196. Mile-end Old-town, area 679 acres; population 105,573, increase 12,421; houses, 14,047, increase 1,011. Poplar, area 2,335 acres; population 156,525, increase 40,149; houses 20,487, increase 4,225. St. Saviour, Southwark, area 1,119 acres; population 195,111, increase 20,062; houses 24,211, increase 897. St. Olave, Southwark, area 1,503 acres; population 134,586, increase 12,188; houses 17,324, increase 995. Lambeth, area 3,941 acres; population 253,569, increase 45,227; houses 35,082, increase 5,953. Wandsworth, area 11,488 acres; population 210,397, increase 85,337; houses 30,754, increase 11,600. Camberwell, area 4,450 acres; population 186,555, increase 75,249; houses 27,306, increase 9,534.

The increase and decrease in the numbers of inhabited houses and population in the Registrar's districts and the sub-districts of London fluctuate considerably. Between 1861 and 1881 Fulham and Wandsworth districts have had the lead. The Wandsworth district has increased in population 198·8 per cent. during the twenty years, and has increased 68·2 per cent. in the last ten years. Fulham has increased 188·6 per cent. in the twenty years, and 73·8 per cent. in population in the last ten years. Wandsworth is associated with Battersea, that shows an increase in population of 53,232 for the last ten years, with an increase of 6,681 in the number of inhabited houses; Streatham, that has an increase of 11,070 in its population; Clapham, that has added 9,031 in the ten years; with Wandsworth itself, increase 8,222; and Putney, with an increase of 3,782. It will be seen that the mere increase in the population of some of these sub-districts greatly exceeds that of many county towns. Fulham is associated with St. Peter's, Hammersmith, and St. Paul's, Hammersmith. The increase in the population of the last-named was 28,291; that of Fulham itself, 19,545. The increase of Kensington town during the decennial period was 28,482. The decrease of 6,684 in population of St. George's, Hanover-square, may excite surprise that should survive the reflection that St. John's and St. Margaret's, Westminster, are in the district, and should be associated with the Westminster district proper, in which Tothill-street and its purlieus have been swept away to be superseded by Victoria-street, the Royal Aquarium, and other modern buildings. The population of the Westminster district, including Golden-square, Berwick-street, and St. Anne's, Soho, sub-districts, has been reduced during the ten years from 51,181 to 46,456, decrease 6,684; and the inhabited houses from 4,554 to 4,281, decrease 273. This is exclusive of a reduction in the population of St. John's, Westminster, of 2,996, and of St. Margaret's of 3,177. In the St. Pancras district it may be remembered that Agar-town and Somers-town, and many unclean streets and quarters, were swept away to give sites for the grand station and hotel, the goods and coal stations, and other works of the Midland Railway Company. In the Somers-town sub-district the population has been reduced since the preceding census from 38,533 to 34,355, a decrease of 4,178, and the inhabited houses have fallen in number from 3,857 to 3,198, a difference of 659. In the same district, however, Kentish-town has, with its 87,388 of population, gained 19,190 in the last ten years, and has made up the number of its inhabited houses, 10,030, by adding 1,499 to them in the same period.

Large areas in various parts of London have had their populations dispersed, and the inhabited houses upon them razed, during the last ten years. This has been notably the case in the City, the localities of Holborn, Saffron-hill, Snow-hill, Whitecross-street, Clerkenwell, St. Clement Danes, St. Martin's-in-the-fields, Shoreditch, Cripplegate, and Castle Baynard.

In Cripplegate the population has been reduced during the ten years from 13,638 to 7,185, a reduction of nearly half; the houses for habitation, 818, are fewer by 756 than they were ten years ago. In Castle Baynard sub-district the population, 9,947, has been reduced by 5,502, and the inhabited houses, 1,360, by 584. In the Holywell sub-district, Shoreditch, the population has been reduced from 12,430 to 7,370, and the dwellings from 1,529 to 988. In Whitecross-street sub-district, with a present population of 9,217, the reduction has been 4,575, and the habitations have diminished from 1,430 to 835, a difference of 595. In the St. Clement Danes sub-district the population of 1871 of 10,723 has been succeeded in 1881 by the reduced number of 8,547, a decrease of 2,176, and the inhabited houses, 1,036, by 815, a reduction of 221. The sub-district of St. Martin-in-the-fields, Strand, has now a population of 17,447, whereas in 1871 it was 21,238; the inhabited houses are now 1,745, then they numbered 2,083.

The objects for which some of these districts have been depleted of their population and the inhabited houses swept away, and the uses to which the cleared areas have been applied, will be readily apparent to any one acquainted with London.

Of the twenty great English towns mentioned in the weekly reports published by the General Register Office, all have increased in population during the last ten years, except Manchester proper. The increase has been in Salford at the rate of 41·2 per cent.; Oldham, 34·8 per cent.; London proper is tenth in order, with an increase at the rate of 17·2 per cent.; Plymouth is lowest, with an increase of 9·2 per cent. The increase in the population of the United Kingdom from 1871 to 1881 has been at the rate of 10·7 per cent. Taken separately, of England, 14·5 per cent.; Wales, 11·7 per cent.; Scotland, 11·1 per cent.; Army, Navy, and Merchant seamen abroad, 12·4 per cent.; and *decrease*, Ireland, 4·7 per cent.; Channel Islands, 3·2 per cent.; and Isle of Man, 1·0 per cent. Of the thirty-eight English and Welsh counties that have increased in population, Surrey stands first, with an increase at the rate of 31·5 per cent.; Glamorgansbire, 28·6 per cent.; Durham, 26·6 per cent.; Lancashire is sixth, with 22·5 per cent.; Kent thirteenth, with 15·2 per cent.; Middlesex fourteenth, with 14·9 per cent.; and Bucks, last on the list of thirty-eight counties, with an increase of 0·2 per cent.

There are some gratifying indications of revived prosperity in certain towns and districts given by the returns of the last census. In 1871 Coventry showed a falling off in population of 1,538; Macclesfield had a decrease of 2,198 as compared with 1861; and Congleton a decrease of above 1,000. The staple industries of these places were supposed to have suffered from the commercial treaty with France; they seem to have partly recovered. At the last census the population of the Parliamentary borough of Coventry was 47,366, being 6,018 in excess of that of 1871; houses, 10,399,—increase, 1,065. The Parliamentary borough of Macclesfield has, in 1881, a population of 37,620, increase 2,050; houses 8,547, increase 105. Congleton, superintendent registrar's district, has a population of 38,010, increase 1,729; houses 7,813, increase 328.

Middlesbrough-on-Tees and Barrow-in-Furness are remarkable instances of growth in population and increase in the number of houses, their growth being attributable to the mineral wealth of the districts around them. In 1831 the population of Middlesbrough was 754; in 1861 it was 18,992; in 1871 it was, in the Superintendent Registrar's district, 60,037; and 1881 has reached to 89,871; increase in ten years, 29,834; houses 16,504, increase 6,005. Barrow had only a small number of scattered cottages about forty years ago. In 1861 it had a population of 3,300; in 1871 increased to 18,774 in the Superintendent Registrar's district; and to 47,276 in 1881,—increase 28,502; houses 6,787, increase 3,975.

The above are a few illustrations of disturbance or movements of population, for the greater part exceptional, and attributable to other causes than those upon which "natural increment" is calculated, viz., the birth-rate and the death-rate.

THE LONDON AND NORTH-WESTERN DIVIDEND, ACCOUNTS, AND HALF-YEARLY MEETING.

THE meeting of the London and North-Western shareholders on the 20th of August was remarkable for a very clear and manly speech from the chairman, Mr. Moon, the interest of which is far wider than even its importance as illustrating the movement of one of our chief companies might lead us to anticipate. Mr. Moon had to speak of those adverse circumstances against which the North-Western has had to struggle during the past six months, in common with other companies. He had also to speak of other matters which, while special to this great line, are of the greatest moment as illustrative of the financial, and to some extent of the social, disorders which have afflicted the entire kingdom.

As to one or two points, the special interest of the railway shareholders, as represented by the chairman, may be regarded as to some extent balanced against the public interest. Such is the case with regard to the tax upon passengers. Taxes, unfortunately, must be paid; and while we are spending 84,000,000*l.* per annum, Chancellors of the Exchequer must look sharp after all sources of revenue. It is Mr. Moon's contention that they look too sharply after the quota from his line. As to that we shall not venture to express an opinion further than to the effect, that if the law requires that a third-class passenger shall be taxed if the passenger is carried from terminus to terminus of the line without stopping, and not taxed if he stops at every station, such a law is not only contemptibly peddling, but is in direct opposition to public policy. Companies ought, in the public interest, to be encouraged to run as many through trains as possible. No less is it in their own interest to do so (although we hesitate to put that argument into the head of the tax-gatherer), as every stoppage of a train is a direct source of loss, at the same time in locomotive power, in maintenance, and in locomotive wages. Nineteen thousand pounds, the chairman complains, which ought to have gone into the pockets of the shareholders as dividend, are thus diverted by sharp practice into the coffers of the State.

If the taxpayer and the railway proprietor may be disposed to regard this question of railway taxation from opposite standpoints, the chairman of the London and North-Western Railway will receive even less sympathy when he mourns the rise of 2d. per ton in the price of coal, and of 12s. per ton on that of steel rails. No doubt, working cost and maintenance of way are augmented by this small rise of price. But any indication of improvement in trade is too eagerly looked for to allow many of us to repine at such signs. For the company, too, we have no doubt that augmented traffic will fully compensate them for such rise in prices. As to the 20,000*l.*, which was the cost of last winter's snows, it goes to the bad, with little compensation. As fighting against these adverse influences, and in presence of a steady decline in the length of the average passage journey, so that 230,000 passengers more have been carried in the half-year for some 7,000*l.* less than on the occasion with which it is compared, it shows very good management on the part of the company to have kept their working expenses down to 52 per cent. of gross income,—the more so, as the average cost on the railways of the United Kingdom for 1880 was, as we recently showed, 54 per cent.

There are, however, points in the speech of the London and North-Western chairman of far graver national import than are those to which

we have referred. The Irish traffic, which has long been increasing steadily at a rate which doubles the revenue from this source every five years, is now declining and failing. 10,000*l.* or 12,000*l.* less was expected to be taken than last half-year. The tourist traffic to Ireland is at an end. Killarney and other lovely spots of the Emerald Isle are without a single visitor. Nor does Mr. Moon find much ground for encouragement as to the future. Recent legislation, he thinks, shows no signs of mending Irish traffic. It is only to the hope of the conviction being produced in the minds of a keen-witted people that absence of law, order, and security brings with it absence of money, that we are encouraged to look forward. Considering the magnificence of the harbour works at Holyhead, and the large sums spent in providing the splendid steamers that now cross the Channel with such speed and punctuality, the failure of the Irish traffic is a bad look out for the railway companies, and a worse for Ireland herself.

Another evil influence to which Mr. Moon attributes a loss of at least 100,000*l.* in the income of the past year, is one which we have ourselves strenuously and persistently combated. It is the influence of those agitators who set class against class, and who teach the working man the false and ruinous doctrine that his interest is opposed to that of his employer. And what is, we confess, of special interest to ourselves, and we trust will prove so to our readers, is the fact that the accounts of the London and North Western Railway for the last half-year illustrate, by the incontestable evidence of figures, the advantage of following, and the disadvantage of neglecting, the advice which the *Builder* so urgently offered, to masters and men alike, on the occasion of the introduction into Parliament last year of the ill-omened "Employers' Liability Bill." Practically that Bill seems to have been an utter failure. Hardly anything has been heard of its operation. But on the one hand, 50,000 of the servants of the London and North Western Railway Company (or to be exact, 49,880 out of 50,000) have adopted our suggestion, and associated themselves with their employers in a mutual insurance bond. Mutual, that is to say, as to the subscription, but confined in its direct beneficiary results to the men. The company have paid 5,000*l.* during the last half-year to the credit of this fund, which is devoted, not alone to the payment of compensation for accident met with in the service of the company *by the fault of the company*, which is all that would be obtained under the Bill, but to give compensation and relief in case of any accident, and also in case of death from natural causes. In fact, the London and North Western Company insure their workmen's lives, as well as provide for compensation in case of injury to life or limb.

A noble piece of beneficence of this kind, proposed by the sound and enlightened policy of the directors, and gladly hailed with practical unanimity by the men, contrasts very forcibly with the efforts of those who have spurned our advice, and thought it wiser to fight for a part than to accept the whole with gratitude.

BUILDING AT CLACTON-ON-SEA.

A LARGE sale of land belonging to the Clacton-on-Sea and General Land Building and Investment Company has just taken place at the Public Hall, Clacton, Messrs. Harman & Matthews being the auctioneers. The auctioneer, in introducing the property, which consisted of 106 building plots belonging to the company, adverted to the continued growth of Clacton, observing that within the last twelve months one portion of the sea-wall had been built, whilst twenty new large houses had been erected at a cost of from 12,000*l.* to 15,000*l.* Three out of the four miles of railway which is to connect Clacton with the Great Eastern Line was laid with the metals, and the line was to be opened before another season. There was a large attendance at the sale, and nearly the whole of the lots were disposed of at prices varying from 150*l.* to 200*l.* each.

Ramsgate Promenade Pier.—The new promenade pier at Ramsgate was opened the other day. It is situate at the eastern end of the town. The engineer was Mr. Henry Robinson, of Westminster, and the contractors were Messrs. Head, Wrightson, & Co., of Stockton-on-Tees.

THE PETROLEUM SPRINGS OF GERMANY.

IT is some years since the probability of finding petroleum in the North of Germany was first mooted. But people were very incredulous, and pooh-poohed the idea, putting the alleged discovery down to the inventive genius of some speculator. From information now published it appears that those who believed in the existence of petroleum in Germany were right, after all, for petroleum winning has now become an accomplished fact. Our German correspondent writes to us respecting the discovery, and our readers may be glad to hear what he says.

Twenty miles from Hanover, on the Hanover and Brunswick Railway, there is situated the little town of Peine, whose name is well known also beyond the borders of the province by its industrial establishments. The quiet streets of this village-town have suddenly become full of life; each railway train brings swarms of strangers, drawn thither either by curiosity or speculation. Years ago, boring experiments were made in the Lüneburger Haide, north of Peine, with a view of tapping petroleum springs; large sums were expended, but success came not, whether from ignorance or incompetence, or from dishonest motives, cannot now be determined. Thus all confidence in the existence of profitable petroleum springs in the locality had fled, and the favourable news which last spring brought with it met with many doubters. Suddenly, a few weeks ago, an event happened which, indeed, removes all doubt, and which has caused the greatest sensation far and wide. A spring was intercepted of a yield and volume such as has not been exceeded even in Pennsylvania. Strangely enough, those results were obtained at the same spot where formerly borings, notwithstanding very heavy expenditure, were made unsuccessfully.

"Oelheim,"—Oil Home or Ham; such is the name of the new colony,—is situate about six miles north of Peine, midway between the Hanover and Brunswick and Berlin and Lehrte Railways. A good road, most of the way macadamised, like all public German roads, and, like them, shaded by fruit or ornamental trees, leads there from Peine. At first we have to the right and to the left splendid cornfields waiting for the reaper, and green meadows; the soil is fertile, and nothing indicates to the traveller that he is on the margin of the Lüneburger Haide, that large moorland of Hanover. Suddenly the picture changes. We behold dry sand soil, the only flower on which is a heather, the red Erica; trees are scarce, here and there small clumps of firs, or single juniper trees. On turning a bend of the road, we reach one of those long-stretching hills which cross the country like waves, and see a large conglomeration of wooden buildings before us. Iron towers rise in the air; by the side of them are wooden pyramids, also low sheds with iron chimneys, from which black smoke ascends; and, finally, small wooden houses, containing offices, living-rooms, and taverns. This is Oelheim, the much-talked of Petroleum Dorado of Germany. If we enter the principal thoroughfare,—we could not by any stretching of the meaning of the term call it a street,—we have on the left the towers and pumping works of the Deutsche Petroleum-Bohrgesellschaft (which has its seat at Bremen); on the right, the establishment of a private undertaking, that of Herr A. M. Mohr. Both dertaking, that of Herr A. M. Mohr. Both undertakings are close together, and are confined to a very small area, while at a greater distance we see the boring and pumping towers of other companies and single proprietors. The life and the traffic are the same as in other large industrial establishments.

The borings were at first carried on after the American system. Iron towers of a height of 75 ft. were erected, rope boring with so-called slide-cheeks being employed. This mode of procedure has hitherto not answered, and boring from wooden towers 56 ft. high by means of rods and Fabian's instrument was resorted to. The bore-holes were then lined with pipes, at first of wrought-iron; but now pipes of riveted sheet-iron one-fifth of an inch thick are used, of a diameter of 16 in., decreasing at a depth of 216 ft. to 8½ in. The borings have disclosed the following geological formation. Down to a depth of 33 ft., fine sand, mixed with erratic blocks, was met with; then came 23 ft. of bluish-grey clay, and 10 ft. of blue clay with limestone layers. From 66 ft. down to a depth of 115 ft., argillaceous marl was found; 16 ft. of rock was next encountered, and finally 26 ft. of hard sandstone rock, when the first traces of oil showed themselves. From 157 ft. down to 177 ft., considerable quantities of petroleum were present in a formation of sandy clay. Descending still deeper, the strata vary very much at the different borings, but porous sandstone, black and brown sand, and especially a layer of gravel, are principally met with, which latter is very rich in oil.

Operations are carried on at present, or will be carried on shortly, by (1) the Deutsche Petroleum-Bohrgesellschaft; (2) Herr A. M. Mohr; (3) Herr Kleissen, a civil engineer of Bremen; (4) Herr Arnemann, of Hamburg; (5) an English company; (6) a new German company, under the management of Herr Wrede, a distiller of Peine. The two latter companies are at present forming, but intend commencing boring operations at once. Herr Arnemann has commenced a bore-hole, while Herr Kleissen has been working for some time; the latter has bored four holes, of which two are not yet completed, one is pumping oil, and the fourth is lying idle. The Deutsche Petroleum-Bohrgesellschaft has driven twenty boreholes; eight of these are pumping petroleum, five are being driven, and seven may be looked upon as failures, in other words, useless for extracting petroleum. Of especial interest are the operations carried on by Herr Mohr, because in his plot the rich spring mentioned above was met with, the yield of which caused a veritable "petroleum fever" at the Bremen Exchange. Herr Mohr has driven four bore-holes. No. 1 has a depth of 295 ft., No. 2 of 230 ft., No. 3 of 226 ft., and No. 4 of 223 ft. The so-called "spring-well" was intercepted in No. 3 boring. The depth of the pump there is 180 ft.; its diameter is 2·36 in., its stroke 35 in. Its name of "Springquelle" originated in the fact that, at the spring being just struck, the subterranean gases exerted such a pressure as to force the petroleum out of the pipe in a thick jet. The force of the gas is still powerful enough to send the oil above the pump-chamber. With a speed of sixty strokes per minute, the pump raises within the twenty-four hours the astonishing quantity of 20,000 imperial gallons of the liquid. The latter consists of one-third of brine and two-thirds of oil. The oil yields, after refining, 45 per cent. of pure, very light-coloured petroleum, stated to be of better quality than the American standard oil, and 50 per cent. of fine lubricating oil, several times the value of petroleum; 5 per cent. are lost in refining. In order to estimate the extraordinary value of this spring, it should be mentioned that the other bore-holes sent forth a liquid yielding only 2 to 3 per cent. of oil, and that even with this small percentage operations are stated to pay very well. While in the case of the latter the liquid appears grey or yellowish brown, and is to a certain extent transparent, Mohr's spring No. 3 displays a dense opaque stream of yellow ochre colour. Numerous bubbles betray the heavy gases escaping with the brine and oil. The liquid flows in a jet of the thickness of an arm in a large iron basin, having a small hole at the bottom. Through this the water escapes, while the lighter oil floats on the top, and is drawn off into another reservoir. Separated from the water, the oil assumes a lustrous dark-green colour, and requires, in order to be separated from stray earthy matter, to be conducted to a third basin, whence it is pumped by hand direct into barrels. The outflow from this spring has hitherto been so heavy that the lucky owner has had to stop pumping at the other boreholes,—which, however, flowed just as copiously as before,—because sufficient barrels could not be made quickly enough for holding the oil.

Up to the present time, the oil obtained had to be sent to Hämelingen, near Bremen, to be refined. A refinery will shortly be opened at Peine, erected by the Deutsche Petroleum-Bohrgesellschaft, the oil being transmitted in iron pipes direct from Oelheim.

Thus far our correspondent. It is impossible to say how far the sanguine hopes which have been raised in connexion with those young undertakings will be realised. It ought to be known, however, that the former hap-hazard experiments have been abandoned, and that the works are now carried on in a rational manner in the new oil district. The discovery has caused the greatest sensation all over Germany. It is already predicted that in the future the latter will be able not only to provide for her own wants from the Hanover springs, but also to export a good deal of petroleum. Germany has always been a very large importer of the

oil from America, and the importance of the discovery of these springs is evident. The companies of Pennsylvania will no longer be able to monopolise the market for this article, sending up prices at their will.

As on all similar occasions, speculation in this article will soon be rampant. Petroleum companies engering is only just beginning in Germany, but it is impossible to say to what length it may go.

MONUMENTAL BRASSES.

Amongst the several classes of sepulchral effigies which form such noticeable features in our English churches, perhaps none have such peculiar interest as the monumental brass. This is especially the case because this class of memorial is now almost exclusively confined to England, the fine examples which existed on the Continent having nearly all fallen victims to fanatics and revolutionists. Having taken great interest in these records of Mediæval art, and possessing a fine collection of "rubbings" obtained from various parts of England, I venture to think that a paper on the subject will not be without its interest to readers of the BUILDER.

It will be best to divide the subject into two main classes, giving (1) some account of the art of brass engraving during the Middle Ages; and (2) a description of some of the more typical specimens remaining in this country.

As the art was known on the Continent a long time before it was introduced into England, so also when English artists turned their attention to brass engraving, they used exclusively the "latten" or "laton" plate, brought from Flanders, and taking its name, most probably, from Cedalonia or Calabria. This importation of brass plate continued for a long time, the earliest notice of its being made in England being a patent granted 1565 by Queen Elizabeth to Wm. Humfrey, assay master of the Mint. However, although the raw material originally came from Flanders, but comparatively few examples of Flemish brasses are to be found in this country, nearly all being the work of English artists. The few that were engraved in Flanders and afterwards sent over, are elaborate in the extreme, and generally consist of a square plate, the figure being only divided from its surroundings of canopy, inscription, &c., by a diaper pattern, and not executed on a separate piece of latten, as is the case in nearly all English brasses. The finest and best known Flemish examples are to be found at St. Alban's Cathedral, 1360; St. Margaret's, Lynn, 1349, 1364; North Mimms, Herts, 1360; Elsing, Norfolk, 1347; Wensley, Yorkshire, 1360;* Newark, Notts., 1361; and elsewhere. As is seen by the few examples quoted, they are chiefly of the fourteenth century. That at St. Alban's is an unusually fine specimen, commemorating Thos. de la Mare, abbot, and measuring 9 ft. 3 in. by 4 ft. 3 in.; the whole of this large surface being engraved. This abbot is in full pontificals, with mitre, staff, &c., the hands being crossed at the wrists. The canopy and super-canopy are extremely rich, exhibiting figures of St. Peter, St. Paul, Offa, king of Mercia, &c. The two Lynn brasses are almost as fine, one being to the memory of Adam de Walsoken and his wife, and the other to Robt. Braunche and his two wives, the three figures being nearly of lifesize. This latter has at the base a fine representation of the "Peacock feast" given to Edward III. when on a visit to Lynn.

The best brasses produced in England were, most probably, the work of one or two guilds of engravers. The only examples which bear any guild or artist's mark that I am aware of exist at Westley Waterless, Cambs., 1325 (the letter N reversed, with a mallet), and Trotton, Sussex, 1419 (the N alone), on the splendid brass of Lord Camoys and lady. These guilds seem chiefly to have been settled in London, though in the fifteenth century there were many brass engravers in the art-loving city of Norwich, being, as it was, the chief town of a district which has produced some of the noblest specimens of Mediæval work. Certain peculiarities seem to indicate the former existence of local guilds, as are shown in various brasses in the counties of Northampton, Warwick, and Suffolk.

There are no brasses now remaining in England of earlier date than the thirteenth century, and they are of very rare occurrence; by far the greater number belong to the fifteenth century, and are to be met with in the eastern counties, especially in Norfolk and Suffolk. The earliest example is at Stoke d'Abernon, Surrey, 1277, and commemorates Sir John d'Abernoun, showing his figure protected by the chain mail of the period, the feet resting on a lion, and the left arm bearing a shield with the arms of the deceased, viz., *az.* a chevron *or*. Another brass of this period is the celebrated one to Sir Roger de Trumpington, in the church of Trumpington, near Cambridge, dating from 1289,—a valuable example of the costume of a Crusader. There is also a very curious little brass, a demi-figure to Sir Roger de Baslingthorpe, in the Lincolnshire church of that name, dating from 1290. This scarcity of early brasses shows how highly they were esteemed when first introduced into England, as their costliness prohibited their general use.

The earliest Continental brass remaining is, I believe, to be seen in the Church of St. Andrew at Verden. It is to the memory of Bishop Yso von Welpe, 1231, representing him, as is usual for bishops, in pontificals. There is also a very fine specimen in the Cathedral of Hildesheim to Bishop Otho de Brunswick, 1279. But beyond these, and a few still existing at Lubeck, Schwerin, Bruges, and Ghent, the Continental churches are practically destitute of these memorials.

As was said before, the practice of engraving a whole plate, dividing the figure from the architectural adornments by diapers, &c., was not followed in England till the middle of the sixteenth century, when we find many small brasses engraved on a square plate, giving, perhaps, a group of figures above, with a long inscription below. This form continued, then, till the art of brass-engraving died out, is common with many other crafts, in the tasteless period of the last century. Brasses of foreign workmanship are, however, easily distinguished from the late English examples by the character and purity of their details.

During the fourteenth and fifteenth centuries the highest resources of the designer's and engraver's art were lavished on monumental brasses, those of the nobility being enriched with their arms, badges, rebuses, &c., while the citizens and merchants were distinguished by their respective tokens and "marks." The brass of Lady Camoys, at Trotton, 1310, was originally powdered over with stars and coronets; that to Sir John Say and his wife Elizabeth, 1473, at Broxbourne, Herts, still retains the enamelling of the arms on the tabard and kirtle, while the beautiful memorial to Laurence de S. Maur, rector, 1337, at Higham Ferrers, Northants, is a very fine specimen of a brass with a canopy and super-canopy, both these adjuncts being adorned with figures of saints with their proper emblems. Brasses may always be taken as faithful representations of the costume of the period, as is manifest by comparing them with any contemporary portrait or painting, and it seems almost certain that in many cases the identical patterns on the dresses of ladies and collarets of knights were copied exactly. It is curious, however, that the artists who designed the brass were careful to avoid depicting the extreme fashions prevalent at the time.

It will now be the place to notice some of the more interesting examples of brasses remaining in England, classing them under the heads of ecclesiastical, military, civil, and miscellaneous, giving also some instances of curious inscriptions.

Brasses of Ecclesiastics.—The majority of brasses before the Reformation represent ecclesiastics habited in eucharistic vestments, the alb, stole, chasuble, and maniple. Bishops are depicted in tunicle and dalmatic, with mitre and staff, the chasuble, &c., being also their principal vestments. Archbishops carry a crosier. There are also many examples of ecclesiastics habited in the cope, a vestment more especially used for processions and for functions other than sacramental. The earliest example of a brass to the memory of a priest existed some years ago in the church of Oulton, Suffolk, but, shameful to narrate, was stolen (I believe in 1840), and has never been recovered. Its date may be fixed at 1310 (3rd Edw. II.), and it was probably a memorial to one of the Bacon family. It represented the deceased in vestments of beautiful design, the hands placed as in prayer (an attitude adopted in almost all pre-Reformation brasses), and the feet resting on a lion. Other early specimens of priest brasses remain at Chinnor, Oxon, 1320; Woodchurch, Kent, 1320 (a beautiful figure in the head of a cross); Brigton, Northants, 1340; Denham, Bucks, (now, I believe, lost), 1360; Brundish, Suffolk, 1375; and Hellesdon, Norfolk, 1389. In Hereford Cathedral is a beautiful brass to Bishop Trellick, with canopy, dating from 1360. There is a very curious brass in Horsmonden Church, Kent, to John de Grovehurst, *c.* 1340, in vestments, with a scroll in the hands inscribed with a text.* Brasses to priests have not generally a long inscription, but simply a pious wish, as "Fili dei miserere mei" engraved on the breast of the figure at Higham Ferrers, quoted before; or "Hic jacet magi—qui obiit—die Julii Añ dñi MCCCCXX cujus aie ppciet Deus Amen." This last is an inscription to be met with in almost every church where there is a brass, and seems to have been a universal form of epitaph. But scarcely any brass, whether ecclesiastical or otherwise, of the fourteenth or fifteenth century indulged in a long inscription, this being a weakness not developed till post-Reformation times, when the merits and not the shortcomings of the deceased were written for the information of posterity. One of the finest brasses to a prelate is that to Archbishop Robt. de Waldeby, 1397, in Westminster Abbey; he bears the crosier, and is in the attitude of bestowing a benediction. The following list gives some of the more interesting memorials of bishops:—Archbishop Grenefeld, 1315, York Cathedral; Archbishop Cranley, 1417, New Coll. Oxon.; Robert Wyvill, Bishop, 1375, Salisbury Cathedral (a very fine brass); Bishop Bowthe, 1478, East Horsley, Surrey; Bishop Goodrich, 1554, Ely Cathedral, &c. The pall (similar to the Greek ὠμοφόριον) is peculiar to archbishops; its shape is similar to the pall blazoned on the arms of the see of Canterbury. Abbots are represented with staffs: examples remain at Westminster, Abbot Estney, 1498 (a very beautiful memorial), and Dorchester, Oxon, 1510. Only two brasses of abbesses remain, they are to be seen at Elstow, Bedfordshire, 1530, and Denham, Buckinghamshire, 1510. Sometimes the priest is shown holding the chalice with the consecrated wafer: examples are to be seen at Higham Ferrers, 1498; Cobham, Surrey, 1510; Broxbourne, Hertfordshire, 1465; and many other places. Ecclesiastics wearing surplices only are rarely depicted, a notable exception being the splendid brass to Thomas Nelond, prior of Lewes, 1433, Cowfold, Sussex. Priests are sometimes shown wearing the almuce or amice, a kind of tippet or hood of white fur, which became altered in the fifteenth century by the addition of a cape and pendents. Good specimens of this habit are to been seen at Hackney Church, in the brass of Dr. Urswick, 1521, and at St. Cross, Winchester, in the memorial to Dr. Richard Harward, "decretorum doctor," 1493. Ecclesiastics in academicals are rarely met with in parish churches, though our two Universities have fine examples in their college chapels. In St. Benet's, Cambridge, is a very interesting brass of a doctor of divinity, habited in cassock and hood, while other similar brasses are to be seen at New Coll. Oxon., 1441, 1468, and St. Martin's Outwich, London, *c.* 1500. It would require a much more comprehensive article than this to give even a short description of the various kinds of brasses placed to the memory of ecclesiastics, and I will leave this part of the subject after a few remarks upon brasses of members of religious orders. Engraved memorials to monks are extremely rare, owing to the rules of poverty by which their order were bound; but examples are to be seen at St. Alban's Cathedral to Robert Beauner, *circa* 1470; Cowfold, Sussex (Cluniac Prior), 1433; and Halvergate, Norfolk, *circa* 1460. These memorials represent the deceased in the habit of their order. Figures of priests are sometimes placed in the head of a floriated cross, but some of these beautiful brasses will be noticed further on.

Military Brasses.—The two early military brasses at Stoke d'Abernon and Trumpington, have already been mentioned. The one or two other cross-legged effigies that remain are extremely interesting. They are the following:—Sir Robt. de Bures, 1302, Acton, Suffolk; Sir Robt. de Setvans, 1306, Chartham, Kent; Sir — Bacon, 1320, Gorleston, Suffolk; Sir — Fitzralph, 1320, Pebmarsh, Essex; and Sir Hugh Hastings, 1347, Elsing, Norfolk. Each of these beautiful memorials represents the deceased

* Since this paper was written I have heard that this fine brass has lately been stolen!

* This memorial has lately been "restored" by repolishing and refilling the incised lines with mastic; both processes possessing very doubtful advantages.

in hawberk or suit of mail, with bliaus or surcoat, sword, and shield blazoned with the family arms. The Pebmarsh and Elsing examples have a slightly different armour, being a little later in date. In the Trumpington and Chartham memorials the figures have curious ailettes or little wings edged with fringe, and sometimes charged with the arms of the wearer, as at Chartham, where these appendages bear the winnowing-fan, the arms of Setvans. It would be impossible within the limits of this paper to give an account of the changes in the form of armour during the fourteenth, fifteenth, and sixteenth centuries: so I will merely point out some of the finest examples of military brasses of these periods. At Westley Waterless, Cambs., is a very fine brass to Sir John de Creke and lady, *circa* 1325, depicting him in mail with bascinet, or pointed helmet, and camail (the portion of mail round the throat and shoulders). Rowell spurs are first seen here. In the reign of Edward III. the jupon was worn over the hawberk; it was a sleeveless garment of silk or velvet, sometimes finely embroidered with armorial bearings. At Bowers Gifford, Essex, is an early example of the jupon in the brass of Sir John Gifford, 1348; Sir Hugh Hastings, at Elsing, also wears this surcoat, broidered with the maunch of the Hastings family. The only remaining example of a military brass of the reign of Edward II. lies in the church of Minster, Isle of Sheppey. It commemorates Sir John de Northwode, and depicts him in a bascinet with enriched border, and camail of banded ring-mail. There is a chain attached to the breast for the purpose of securing the tilting-helm, and the shield is suspended by a strap so as to cover the sword. It bears the arms of Northwode, *erm.* a cross, *engr. gu.* The figure of his lady lies beside him, her head supported by a diapered cushion, and her throat surrounded by a very curious wimple. There are some splendid examples of military brasses dating from the latter end of the fourteenth century. At Aldeburgh, Yorkshire, is a fine memorial to William de Aldeburgh, *c.* 1390, showing him in bascinet and camail, with a short habergeon, and jupon enriched by a handsome embroidered bawdric or belt. The arms of Aldeburgh are blazoned in the jupon, and on the shield. At Southacre, Norfolk, is another fine specimen of this class in the memorial to Lord John Harsick and his lady, 1384. He holds his wife by the right hand, his left resting on his sword. The mail shirt is seen slightly below the jupon, which is charged with the Harsick arms,—a chief indented. Above, as an ornament, is the tilting-helmet, with the cointisse and crest,—in a hoop or a bunch of turkey feathers. In Cotman's "Brasses" is an etching of the brass of Sir Miles Stapleton, 1364, from Ingham Church, Norfolk (now lost), which is a valuable example of studded-mail or small round plates of steel secured to a lining of pourpoint. There is a figure in Harrow Church having the thighs defended by this class of armour, and also in Watton Church, Herts, 1361. At Little Casterton, Rutland, is a very beautiful brass to Sir Thomas and Lady Burton, 1382, the knight wearing bascinet, camail, and jupon, and also the collar of SS. His lady wears a most curious square netting to the hair, with a long cloak and girdle. In the magnificent memorial to Sir Robert Swynborne and his son Sir Thomas (1391 and 1412), in Little Horkesley Church, Essex, we have two kinds of armour depicted in the same work of art, the father wearing the jupon sec, and the son the newly-introduced plate armour, with skirt of taces or plates of steel, overlapping upwards and protecting the thighs. Sir Thomas wears the collar of SS. These two fine figures lie under beautiful canopies.

In Baginton Church, Warwickshire, is a most admirable brass to Sir Wm. and Lady Bagot, 1407. He wears bascinet and camail, with collar of the SS., jupon and gauntlets, with armour for the arms and legs. His arms,—a chevron between three martlets,—is broidered on the breast. Lady Bagot wears a kirtle, cotehardie, and fur-lined mantle. The armour of the knight is beautifully engraved and chased. Many splendid brasses of this period are to be met with, some adorned with magnificent canopies. There is a curious memorial at Harpham, Yorkshire, to Sir Thomas de St. Quintin, 1418, in a form of plate-armour, with a rather grotesque orle or chaplet round the bascinet. The following is a short list of fine brasses of this date:—Sir Nich. Dagworth, 1401, Blickling, Norfolk; Sir Wm. Fienlez, 1402, Hurstmonceaux, Sussex; Sir Roger Drury and lady, 1405, Rougham, Suffolk; Sir Reg. Braybrook, 1405, Cobham, Kent; Sir Thos. and Lady Marsyngherde, 1405, Gunby, Lincolnshire; Earl and Countess Beauchamp, 1406, St. Mary's, Warwick; Sir Simon Felbrigg, K.G., and lady, 1413, Felbrigg, Norfolk. Modifications of plate-armour continued in vogue for a century or more; in fact, until that mode of defence was abandoned. The figure of Walter Greene, esq., 1450, at Hayes, Middlesex, has a skirt of taces or plates, cut into the shape of escalops; likewise the effigy of a knight, *c.* 1450, Isleworth, Middlesex. There are some good instances of figures in tabards remaining in different parts of England. Sir Ralph Shelton, 1423, at Great Snoring, Norfolk, was depicted wearing one; but when I visited this church two years ago, his figure had disappeared, though I believe the brass was there a few years ago. At Childrey, Berks, the effigy of Sir Wm. Fynderne, 1444, wears a tabard with the arms,—a chevron between three cross crosslets *fitché*. The sons of John Ansty, esq., 1465, in his interesting brass at Quy, Cambs., are shown habited in tabards.

At the beginning of the sixteenth century the armour became degenerate in shape, many of its details being absurdly exaggerated, as in the case of the elbow-pieces. At Assington, Suffolk, is the figure of a knight, *c.* 1500, clad in armour composed chiefly of overlapping plates. He wears long flowing hair, and the sword is slung immediately in front of him. The effigy of Sir Humphrey Stanley, 1505, at Westminster Abbey, is a good example of late armour. One of the very late forms is to be seen at Wrentham, Suffolk, 1593, in the brass to Sir Humphrey Brewster; his ruff shows above the steel gorget. We find military brasses of the seventeenth century, but they are always of little artistic interest, though of value as examples of armour. At Wrotham, Kent, there is a memorial to Wm. Clerke, esq., 1611; at Margate, Kent, one to — Cley broke, esq., 1600; St. Columb, Cornwall, John Arundel, esq., 1633, &c.

Brasses of Civilians.—These are less frequently met with than those of ecclesiastics or knights, though some are of great interest. I shall include brasses of ladies under this head. The earliest existing example is the very elegant memorial to Margaret Lady de Camoys, 1310, at Trotton, Sussex. She is habited simply in a long robe or dress with loose sleeves, while the tight sleeves of an under-tunic appear reaching to the wrists. The head is covered by a coverchef or handkerchief. About 1340 the figure had nine shields of arms "powdered" over the outer tunic, but these are now gone. Ten years later than this is the very beautiful brass to Joan de Cobham, in the church of that name, Kent. She is habited in an almost similar garb, her figure lying under a fine canopy with small shafts and pinnacles. At Taplow, Bucks, is an extremely beautiful brass to Nicholas Aumberdene, 1350, the effigy being placed in the head of a floriated cross. The costume is that usually worn in the reign of Edward III. We have another even more beautiful example at Hildersham, Cambridgeshire, 1379, where the figures of Robert de Paris and his wife kneel on either side of a floriated cross, in the head of which the Most Holy Trinity is represented. At King's Sombourne, Hants, is also a curious figure of a civilian, *c.* 1380. But it will be best just to point out some of the most interesting features to be met with in brasses of civilians of all classes. Merchants are often distinguished by the marks of their respective "staples,"—many examples are to be seen in the Norwich churches. Notaries are shown with their ink-horn and pen case,—good specimens exist in St. Mary's Tower, Ipswich, 1475, and at the New College, Oxford. During the fifteenth century civilians are frequently represented with a gypcière or scrip, and sometimes with a dagger. Brasses of figures in shrouds are also common, emaciated figures being occasionally depicted, as at Salle, Norfolk. In late brasses the children are shown kneeling below,—the sons below the father and the daughters below the mother, their figures being much smaller, and generally having a very grotesque appearance. In Elizabethan examples the children are nearly always shown. Having thus slightly pointed out a few characteristics of brasses of civilians, a few remarks on miscellaneous brasses will be of interest. Under this head the cross brasses take a prominent position. These beautiful memorials sometimes have figures either in the head or at the side, or are without these adjuncts. Of the former class, the following examples may be given:—To John Lumbarde, rector, 1408, Stone, Kent; Buxted, Sussex, 1408; Taplow, Bucks, 1350, &c. Of the latter,—to Thos. Chichele and wife, 1400, Higham Ferrers, Northants; to Roger Cheyne, Esq., 1415, Cassington, Oxon; and at Broadwater, Sussex, 1415; St. Mary's, Reading, 1416; Beddington, Surrey, 1425, &c. At Upper Hardres, Kent, 1405, is a figure kneeling beside a shaft supporting a basket, on which are the figures of SS. Peter and Paul. Sometimes a brass consisted simply of a chalice and host, with inscription, as at Baurburgh, Norfolk, and elsewhere; sometimes of a heart, with scrolls and inscription, as at Trunch, Norfolk, and elsewhere; sometimes a coat-of-arms, and often an inscription only. In very late examples skeletons, hour-glasses, and other emblems of mortality are depicted. I must not omit to notice the very peculiar little brass to Wm. Complyn and his wife, 1498, at Weeke, Hants; it consists of an inscription and a figure of St. Christopher carrying the Infant Christ over the river, as runs the legend. Occasionally we find that not over-scrupulous persons have made use of a brass of a predecessor for themselves, reversing the plate and engraving it afresh on the other side; such examples are called "palimpsest" brasses, and may be seen at Cobham, Surrey, 1510 and 1550; Hedgerley, Bucks, 1530 and 1540; St. John, Maddermarket, Norwich, 1440 and 1540, and elsewhere.

Inscriptions.—In early times these were generally of a simple description, beginning with "Orate pro anima," with the name and date, generally ending with, "Cujus anime ppcietur Deus." When English inscriptions became common, they began with "Of your charite praye for the soule of." The early inscriptions were always of a pious and solemn nature, the greatest ecclesiastics being content with a prayer or a quotation from the Scriptures. The Norman-French ones were after this sort:—"Gist ycy Dieu de sa alme eit mercy Ame." At Mere, Wilts, 1398, is the following:—

"Quisquis eris qui transieris, sta, perlege, plora,
Sum quod eris, fueram quo quod es, pro me ppr or ora."

Job xix. 25–27, is sometimes quoted beginning "Credo quod redemptor meus vivit," &c. The earliest English inscription is, I believe, at Newark, beginning "Man com and se how schal all dede be," dating from 1370. A sort of litany is occasionally used, as "Sancta Trinitas unus Deus miserere nobis, Pater de celis Deus miserere nobis," &c. Often they are very terse, as "Jesu mercy," "Lady helpe," or simply "Jesu misere." In later times they became long, and were generally devoid of devotion, and sometimes quaint and humorous in the extreme, with puns on the name of the deceased, with verses, &c.

In concluding this article on monumental brasses, I cannot refrain from alluding to the constant disappearance of whole or part of these most interesting memorials from parish churches. It is almost impossible to visit many churches where such monuments are known to have existed without finding that within late years some have disappeared, never to return again to the sacred precincts where they have lain perhaps for generations. I myself have visited churches at an interval of two or three years, and found on the second visit the whole or some portion of a brass wanting. This is either the result of great carelessness or want of appreciation for the works of our pious ancestors, and often, I fear, through the theft of workmen and others at "restorations." My earnest wish is that these interesting relics of a bygone age may for the future receive the respect due to the monuments of illustrious dead.

ARTHUR G. HILL, B.A.

Working of the Employers' Liability Act.—An important decision under the Employers' Liability Act was given at the Bradford County Court by Mr. Daniel, Q.C., on the 26th ult. A man named Whittaker sued the executors of J. Balmforth, ironfounder, Rodley, near Leeds, for damages for injuries owing to the defendants' negligence. Some time ago a piece of cast iron fell on the plaintiff's foot whilst working at a drilling-machine through the breaking of an eye-bolt which had a defect. The defendants denied knowledge of the defect. The judge held that the defendants were guilty of negligence, and gave judgment for the plaintiff, awarding 156*l.* damages,—three years' wages at 1*l.* per week, the largest amount allowed by the Act.

DOMESTIC ELECTRIC LIGHTING.

AMPLE evidence has been afforded to the inhabitants and daily visitors of the metropolis proper that the illumination of streets, public buildings, and even private dwelling-houses by means of electricity is an accomplished fact. Those who have gone regularly to the City have observed the gradual growth of the numerous systems now employed to take the place of gas as a means of illuminating some of the greatest and most important thoroughfares. Massive iron pillars of different designs have been erected in various positions, and the familiar lamp-post has, *pour le temps*, been completely eclipsed by its more gigantic and imposing brethren. Lamps of large size and curious shapes have been placed on the summit of these supports, and the light produced by the generation and transmission of powerful electric currents has far excelled the ancient coal gas, with whose feeble glimmer we have been content for so long. These trials, as well as the numerous others, viz., the illumination of the Thames Embankment, the various stations on the Metropolitan Railway, the Houses of Parliament, and other buildings and places, although serving in a great measure as experiments, nevertheless point out the practicability of the scheme, and exhibit the numerous advantages which would arise from its adoption for many purposes to which it has yet to be carefully applied. The rise and progress of the electric light may be conveniently compared with the life of its neighbour, the telephone. A few years back, and this latter existed merely as an idea, a scientific experiment. Now we find it recognised as a part of the business, and frequently domestic, outfit. It has become a popular and useful addition to every section, and there is no doubt but that in a few years it will be regarded as an absolute necessity by every one. And so with the electric light. Born in the laboratory, it remained for a lengthened period catalogued with a numerous army of similes, and was classed with them as a mere experiment suitable for display on exceptional occasions only. But with the progress of time came the development of electric light. Attention was drawn to the economics of the subject, and soon improvement upon improvement arose, one after another levelling the path, and overturning one by one the manifold obstacles which had before obstructed it. And there are few, we think, if any, who, seeing these brilliant displays, have gone away with the conviction that the extremities of the subject have been reached, or that there is no further room for development. On the contrary, the subject is but in embryo yet, though daily advancing; and there is little doubt that ere long it will no longer be confined to our great cities and mighty highways, but will find its way into our suburban dwellings and our smaller and more modest thoroughfares. Every one knows, only too well, in many cases, the various unpleasantnesses arising from a use of gas. It heats our rooms to a tropical temperature; it is glaring and tiring to the eyes; it blackens our ceilings and our wall-papers; it eats into our pictures, our books, and our curtains; and, finally, it empties our pockets a good deal more than many of us can afford. It is, however, such a necessity that we cannot do without it, in some form or other. "Comparisons are odious," we are told, but putting electric lighting by the side of gas illumination, the most sceptically-inclined individual must confess the former has a distinct advantage over the latter. First of all, the light is pure white, pleasant to the eyes, possessing no hurtful heating qualities, so that rooms in which it is used are rendered cool and comfortable; it is perfectly harmless and non-injurious to any article of furniture, dress, or art. And then, as regards the economy of the question, as the electric light far surpasses gas-light with respect to brilliancy of illuminating power, it stands to reason that less light would be required than when gas was employed. One electric globe in a room would dispense with half a dozen flaring gas-jets. Another question allied to this point is the fact that one cannot be troubled and annoyed by escapes as in the case of gas, which, owing to the prevalence of cheap and scamped plumbing, are of frequent occurrence. Householders will appreciate this fact fully, we think, for there are many who could point out in their gas account a remarkably large quantity consumed, of which they never experienced the slightest benefit, for the simple reason that during their absence from home for a time some thousands of cubic feet were wasted on the "desert air" through a villanous rent in a pipe. With electricity such contingencies are impossible. Electricity is a fluid, invisible, tasteless, without smell, and undetectable except by special methods. No such accidents as explosions or suffocations, resulting from a tap omitted to be closed, or a hole in a pipe, can take place when electricity is employed. A clean house and a bright, cool, and harmless light are desiderata by no means to be despised: they are necessary to this age of labour-saving appliances and simplification of methods, and so we may look for an accomplishment of our hopes and conjectures in a period not far hence.

The telephone promises to invade the domiciles of our private life, the electric light as a natural consequence will follow, and when once introduced the rest is easily foretold. With a brilliant light on our roadways and a bright glow in our houses we should then understand and appreciate more fully the benefits arising from the use of electricity, and acknowledge its supremacy over our old but cumbrous friend, gas. The electric currents could be generated in central stations conveniently situated and connected with the various houses in the district by subterranean cables. During the daytime when the light was not required the electricity could be made to do useful work in other directions. By means of suitable motors we could work the domestic sewing-machine, or roasting jack, knife-cleaner, sausage-machine, and other household apparatus. Passing the current through platinum or other metal of similar nature arranged in copper tubes we could obtain an amount of heat sufficient for many culinary operations, besides warming our rooms in the winter. In fact, there is no limitation to the uses to which electricity may be applied, and a little thought will soon suggest a round dozen or so. Electricity is such a simple agent to handle that it will unquestionably fill a vacant place in the household, and as soon as its special qualifications become more generally known, will, without doubt, become of such importance as to be wholly indispensable.

A. J. D.

THE WOOD INDUSTRY OF CHINA AND JAPAN.

THIS subject was the theme of a lecture recently delivered by Professor Exner in the Oriental Museum of Vienna. The lecturer described the East, as in many other respects, so also in the matter of the wood industry, as the teacher of the West. He based this assertion on the present use of wood, and although the lecture had special reference to the wood industry of China and Japan, it might have been expected that Professor Exner would have cited some people of ancient times who made a name not only in the wood industry generally, but also in wood-carving. It is well known, for instance, that the Phœnicians carried on an active trade in timber and dye-woods, and that the wood industry and wood-carving of this people produced works of art which, if preserved, would have served as excellent specimens of *chefs-d'œuvre* for our art museums. It should be pointed out here that the wood trade in ancient times was very lucrative, and that the wealth of the Phœnicians created such an amount of envy amongst their neighbours as to cause them to lose their independence within a surprisingly short period. Shipbuilding in the East in former times was entirely overlooked by the lecturer in his paper, but probably he had the intention of merely treating of the present. Moreover, the peoples of the civilised States of Europe of the present day formerly employed wood for a great many objects which are now made of metal, glass, &c. It is only in the half-civilised parts of Russia that articles made of wood are still extensively used in preference to those of other materials, though the former are rapidly disappearing before their more formidable rivals.

The lecturer by no means succeeded in what he attempted to prove, namely, that China and Japan are countries which are far in advance of us in the use of wood, and whose example we ought to follow. It is most certainly a sign of progress that we have discarded the wooden plough, and that we now make hundreds of objects of glass, china, or metal, instead of wood. Professor Exner likewise advocated in his lecture the importation of Japanese woods, resting his case on the peculiar properties of certain descriptions. We need hardly point out that the question of cost of freight is one which plays a very important part in our import trade, and that Europe is able to draw its supplies of wood from sources much nearer home. Professor Exner explained the various properties of Japanese woods, dividing them into four principal groups, namely:—*Pauluvia japonica*, *Pictumeria japonica*, *Plavna japonica*, and *Pseudolarix* (*Coniferæ*), and comparing them with those grown at home. The wood of *Pauluvia japonica*, described as the "wood of woods," occupies the chief place. In the case of *Pictumeria* we have five different forms with distinctly-marked characteristics of the sap-wood (*suchi*) and heart-wood (*acam*) with regard to colour. *Plavna* is distinguished by greater hardness from the former woods, shrinks quickly, is aromatic, and especially suitable for turning. *Pseudolarix* reminds us of the white beech and black fir.

As we have repeatedly remarked on former occasions, although the uses which the peoples of China and Japan make of the stores of wood placed by nature at their disposal are most multifarious, and excite deserved admiration, its varied application by them does not prove that they are ahead of us in its employment. Their technical skill in manufacturing wood into articles of every-day use is very remarkable, but it does not surpass that of Western nations in working far less pliable materials into useful forms. The heavy cost of freight will be a perpetual bar to unmanufactured wood from those quarters of the globe being imported into Europe in any considerable quantities, and thus one of the chief conclusions of Professor Exner's lecture falls to the ground.

THE BISHOP'S FIELD, LAMBETH PALACE.

GREAT praise is due to his Grace the Archbishop of Canterbury for having, even for one day, opened to the crowded population of Lambeth the large unoccupied space of land adjoining Lambeth Palace, known as the Bishop's Field. The rare opportunity was seized with avidity by the thousands of children in the neighbourhood who literally swarmed all Monday in last week into and over the Archbishop's paddock, from which its daily peaceful occupants, a few sheep and some horses, had been temporarily turned into their rustic house, which occupies one corner of the enclosure.

The field, to the general public a *terra incognita*, hidden behind the grim wall in the Lambeth-road, and scarcely known even to those guests of the Archbishop who may have been fortunate enough to be invited to some open-air party in the quiet garden of Lambeth Palace, with its beautiful lawn, old trees, flocks of birds, and quaint Old English seat,—is perhaps the only piece of unoccupied ground still left in Lambeth, where open spaces are so sadly wanted. It seems almost obvious that the "Bishop's Field" should be converted into a public recreation-ground. Objection, undoubtedly, might be raised by the Archbishop, but, desirous as he has ever shown himself to benefit the poor, such a scene as that of last Monday week may have suggested to him how sadly wanted is some open space for the little ones of the crowded district in which the London residence of the Archbishop of Canterbury has for so many centuries been situated. Were it not to some extent violating the strict rules of hospitality, it might be hinted that the Bishop's Field is not kept with that absolute regard to tidiness,—even perhaps to sanitary requirements, a large mud-shored horse-pond, and by no means cleanly cow-house, occupy conspicuous places,—that one would expect to find in a place only separated from the Primate's well-kept gardens by a low-crumbling picturesque red-brick wall.

In competent and experienced hands, wonders might be done with the small yet sufficient acreage of the Bishop's Field, and now that so wholesome an agitation is going on in favour of green spaces in our crowded centres, we could imagine no spot more worthy the attention of those in influential quarters. By judicious management and due consideration it might be made beautiful. With the gray historic walls of Lambeth, the Lollards' tower, and all its memories, the old trees of the Palace garden, the not unpicturesque skyline of St. Thomas's Hospital, the peep of the Thames, and the grand outline of Barry's Houses of Parliament to form the natural features, and the aids which cultivation and art place at the disposition of the landscape-gardener in the present day, the

"capabilities" are great for making the "Bishop's Field" not alone a playground and a breathing-space for the crowded district of Lambeth, but an adornment to the metropolis. The scene presented by the Bishop's Field on the Monday in question was more than sufficiently suggestive of the urgent need of some public open green space in brick-bounded Lambeth.

THE NATIONAL PORTRAIT GALLERY.

A NEW and enlarged edition of the historical and descriptive catalogue of the pictures and busts in the National Portrait Gallery, South Kensington, by Mr. George Scharf, F.S.A., has just now been published, and should have the effect of sending an increased number of visitors to this valuable and delightful collection. It includes an historical sketch of the origin and growth of the Gallery, and various lists to show readily what the Gallery contains. In the preparation of the biographical and descriptive notices, which form the body of the work, Mr. Scharf has brought his special knowledge and accomplishments to bear, and has produced a volume equally instructive and entertaining. So good a shilling's worth of reading, quite irrespective of any opportunity to visit the Gallery (450 pages of it), we can scarcely point to.

We may usefully mention that the collection is open, *free*, any day but Friday, from ten to six in summer and ten to four in winter. The visitors last year appear to have averaged nearly 1,500 per week.

COMING MEETINGS ABROAD.

Astronomical Congress, Strasburg.—Various scientific and learned men of Europe have been invited to meet in a congress which is to assemble at Strasburg in the month of September. In the event of this meeting taking place the result is expected to be a brilliant one, as the observatory of that city is provided with one of the best optical apparatus known. The variety of themes for scientific observations are also said to be of no small interest to the astronomical science. The astronomical phenomena which of late have made frequent appearances, and engaged the attention of scientific men of the universe, will, no doubt, be also subjects for discussion.

International Exhibition, Vienna.—We announced this exhibition in one of our past numbers, and from the farther particulars since received from abroad it is to be gathered that the exhibition is intended to represent the works of art confined to the period which has intervened between the last Vienna Exhibition, 1873, and the present date, and that most active preparations are going on for the promotion of this exhibition. It will consist of architecture, sculpture, drawing, design, engraving, and other congenial arts. The exhibition, which will commence in April, will continue to September, 1882. The managing committee is endeavouring to see that all the nations send their share of the exhibits.

International Phylloxeric Congress, Bordeaux.—The Bordeaux Chamber of Commerce, as well as that of Gironde, together with the municipal bodies of both those cities, and the agricultural and horticultural societies of the latter, having resolved to hold an International Phyloxeric Congress, the committee, composed of the respective bodies appointed for making the necessary preparatory arrangements, announces that the same will assemble at Bordeaux, on account of this city being the centre of the wine-growing districts of France, and that the said congress will have a threefold purpose, viz., (1) to discuss and resolve upon the best means of averting the plague, which is said to be on the increase, even after destroying more than 3,000,000 of hectares of the vineyards of France; (2) to generalise the results obtained in various applications of preventives, and the partial remedies discovered to preserve the plants from attacks, and which are not generally known to the men interested in wine cultivation; and (3) to investigate the possibility, by means of certain measures, including financial ones, of bringing about the reconstitution of the vineyards; and as this object cannot be attained but by the testimony of the scientific men, and without the knowledge of results of experiments made in recent years in France and other countries, the committee appeals to vine-growers, and requests the attendance of the men of science of all nations to favour them with their experience and knowledge for the solution of a problem of so important and general interest. The meeting will commence on the 5th September next.

EXTENSIONS AT THE WIMBLEDON RAILWAY STATION.

NEW MAIN-LINE OFFICES.

THE London and South-Western Railway Company are very considerably enlarging their Wimbledon Station, with the intention more especially of providing greatly increased accommodation for the main-line traffic. The extensions in progress are on the west side, and when the works are completed the station area will be increased to almost double its present extent. Immediately to the west of the up-main-line, a new block of buildings is in course of erection, containing in the centre large and convenient booking-offices, 40 ft. by 20 ft., whilst at the south end of the block there are three commodious ladies' waiting-rooms, for first, second, and third class passengers respectively; and at the north end a spacious general waiting-room, 30 ft. square. The booking-offices and waiting-rooms will be approached on the extreme west side under a covered roof. A new platform, 500 ft. in length and 20 ft. in width, with an asphalte surface, has been constructed, running parallel with the up main-line, a portion of the platform, to the extent of 200 ft. in length, being covered in with an arched-roof of corrugated iron, supported on columns and ornamental iron brackets. What has hitherto been a large open space, immediately on the east side of the down main line, situated between that line and the several suburban or branch lines, has also been utilised for the purposes of the enlarged station. On a portion of this hitherto open area, which is about 40 ft. in width, new offices and waiting-rooms have likewise been erected, and the entire width, to the extent of 200 ft. in length, covered in with a corrugated iron roof, uniform with that on the up-line side of the station; whilst a new platform for the down-line traffic, 500 ft. in length, has also been constructed. Access will be had to the enlarged station by the extension of the existing footbridge over the railway, and two new staircases leading down to the several platforms. The new footbridge has a span of 56 ft., and is carried to the extreme west side of the up-line new platform. It may be added that the whole length of the footbridge over the several lines of rails, from the street approach on the east side of the station, to the west side, is about to be roofed over, and the upper portion of the sides of the bridge will be filled in with glass. When the works now in progress are completed the main-line platforms on the up and down side will each be upwards of 1,000 ft. in length. We understand that the intention of the directors ultimately is to reconstruct the existing old station buildings.

Messrs. Perry & Co., of the Tredegar Works, Bow, are the contractors for the works, which are being carried out under the superintendence of Mr. Medcalfe, one of the company's engineers.

FROM ABROAD.

Trojan Antiquities.—The German press has lately called attention to the fact that Dr. Schliemann has (with the assistance of four officials from the Royal Gallery) arranged the articles found by him during his excavations, in the new Art Museum at Berlin. They are mostly in glass cases (similar to those at the South Kensington Museum), being duly classified and labelled. The golden relics of Trojan grandeur will have a case which is being made with a special view to their security. The collection will then be open to public inspection, under Dr. Schliemann's supervision.

Block Houses.—The Swedish block-houses referred to in our issue of the 27th of August cost 60*l.* each to make, and the freight to Sassnitz was about 8*l.* per house. The total cost of each of them, including erection, with foundation, verandahs, three coats of varnish inside and outside, besides painting the roof, was 135*l.*

Dangers of Lighthouse Building.—The steamer *Nordvakten* lately brought to Stockholm, twenty-two workmen, who had been engaged in laying the foundations of a lighthouse on the Bogskaer, a naked rock in the southern part of the Aland islands, which is, in calm weather, only 15 ft. above the surface of the waves. A sudden and violent storm had sprung up, and in a short time swept away their boats, building materials, and food. After three days' sojourn on the rock, without food or drink, they were fortunately observed, and rescued by the above steamer from their perilous situation.

An Underground Railway is projected for Naples. The plans are already before the municipal council, and will be discussed in detail very shortly. The persons undertaking the work are ready to bear the cost of the construction and the expenses of working the line. It will begin at the Grotto of Posilippo, and will be brought under the Vomero, the Strada di Chiaja, and some other streets terminating at a point near the sea.

A Monumental Bridge is about to be built at Bremen, which will connect the Bürger Park with the wood of the same name. The excavations for the foundations are now being proceeded with. It will be at a high elevation, and will have a roadway over 30 ft. in width, on account of the large converging traffic which is expected in each direction. The ground in the immediate neighbourhood will be raised, and the necessary earth will be obtained from the excavations to be made in connexion with a water-reservoir. The work will occupy from two to three years.

THE FEMALE PREVENTIVE INSTITUTION.

ON the 24th ult. Sir William Rose, K.C.B., Clerk to the House of Lords, laid the foundation-stone of the new chapel and other buildings now being erected in the rear of the Central Home, Euston-road. Mr. Charles Burton, on behalf of the committee, read an address, setting forth that having secured the freehold, justified them in making every possible improvement for the inmates which the space would allow. The committee had had certain difficulties to surmount with respect to light and ventilation, and in both it is fairly anticipated that the result of the exertions of Mr. E. W. Thomas, the secretary, would prove satisfactory. The foundation-stone, which was laid with Masonic ceremony, forms a cinquefoil tablet in the east wall of the chapel. The works comprise a chapel; work-room, 21 ft. by 17 ft.; a dining-hall, 20 ft. by 17 ft.; a newly-constructed kitchen, scullery, store-closet, salting-closet, bath-room, wash-house, laundry, and drying-closet, which is to be so arranged that one fire will not only heat the irons for the workers, but also dry the clothes. The chapel is Mediæval in style, with stained-glass windows, and an open-timbered roof.

The architect is Mr. W. P. Griffith, F.S.A., and the builders are Messrs. Dunford & Langham.

THE NATIONAL MUSEUM, AMSTERDAM.

IN the year 1874 the Government invited in competition plans for a museum for the art-treasures in painting and sculpture dispersed in various establishments belonging, some to the Government, and some to the town of Amsterdam. Four architects who had obtained premiums in preceding international competitions were selected to compete in the present case. They were Messrs. Cuypers, Eberson, Oudshoorn, and Vogel. The jury selected the plan submitted by Mr. Cuypers, and on July 2nd, 1875, his Majesty the King appointed that gentleman architect to the Government Museums.

The first contracts, for the construction of the offices, the laying-out of the grounds, &c., were entered into on November 9th, 1876. Mr. Helsen, of Amsterdam, was the contractor at the sum of 13,095 francs.

On the 14th December, 1876, the contract for levelling the ground with pile-work and brick foundations was adjudged to J. Schoonenberg and C. J. Maks, contractors, of Amsterdam, for the sum of 197,500 francs.

The embankment of the ground, which was very low, occasioned an expense of 75,000 francs for filling up with sand to reach the level of the adjacent streets. On the 24th of May, 1877, tenders for the supply of bricks were sent in, and the contract was given to H. C. Van der Houven van Oordt, of Apeldoorn, for 218,595 francs; and on the 6th of December of the same year, the supplying of the stone, called blue stone, or little granite of the Ourthe, was adjudged to Louis Goffin & Co., of Liège, for the sum of 127,698 francs. In the year

1878 the contracts for the other materials were entered into, and also for the entire construction of the monument with the following builders: A. Boller, of Mannheim, for the stone of Roche-d'Enville, of Savonnières, &c., for the sum of 188,000 francs; to J. Schoonenberg & C. J. Maks, of Amsterdam, for the outside masonry, the woodwork, &c., for 458,000 francs; and to T. Paris Isaac, of Marchiennes, for the metal-work, roofing, and glass-work, for 299,500 francs.

In 1879 the contract for the heating and ventilating apparatus was adjudged for the sum of 47,000 francs, to Geneste Herscher & Co., of Paris. For this latter contract five firms competed. The building is now being roofed in.

The programme of the original competition exacted of the designer the provision of a public way for carriages and foot-passengers across the museum, to facilitate the communication between the old town and the new parts in course of construction. This arrangement gave at the same time a means of dividing the building for different services, the structure being destined to contain,—first, a museum of objects having reference to the national history; secondly, a cabinet of engravings; and thirdly, the picture galleries.

The first floor, spreading over the entire building, is destined for pictures. The ground floor, of which we give the plan, is divided into two sections: to the east or right of the passage is the museum of national history, whilst on the west or left of the passage is to be the cabinet of engravings as well as the library. Each division will have its special director.

NEW PULPIT AT ST. MARTIN'S CHURCH, BRIGHTON.

AT the cost of Mr. Henry Wagner, a pulpit, with lofty canopy, has been erected in the church of St. Martin, Brighton, of exceptional character; we give a view of it. The whole structure, which is of oak, stands upon a plinth of Sussex marble. The plan of the pulpit, a little over 6 ft. in diameter, is based on a heptagon. The two sides towards the wall are, however, replaced by three sides of a smaller octagon. These three sides form the back-board behind the preacher, and unite the pulpit below with the sound-board or reflector above.

The pulpit itself is 7 ft. 9 in. high from the floor level of the church to the book-board, whilst the floor of the pulpit, approached by seven steps, is raised 4 ft. 6 in. from the floor of the church. Upon the marble plinth stands a plinth of oak, from the angles of which rise pillars cut into niches, and carrying the highly-enriched cornice which marks the floor level of the pulpit. In the niches are figures of the four fathers of the church,—St. Ambrose, St. Gregory, St. Augustine, and St. Jerome. Standing as it does in the north-east angle of the nave, and being flanked by the chancel-screen, the other pillars are either invisible or are engaged in the staircase, and are consequently not so richly carved. Between the heads of these pillars depends open carved work of leaves and flowers, treated, as is the whole, in the style of woodwork prevalent in this country in the fifteenth century. The eight pillars just described surround a stouter pillar, or stem, with buttress at the angles, and panels carved in a simple linen pattern on each face. The floor on which these rest is inlaid with olive wood, which was brought by Mr. Henry Wagner from the Holy Land, and cut from off the Mount of Olives. Above the cornice we see the sides of the pulpit. One side is occupied by the stair, four by carved panels, and the other three towards the wall are formed by the back-board, already mentioned. The subjects on the panels, which are carved in low relief,—are St. Paul preaching at Athens, the Sermon on the Mount, St. John the Baptist preaching in the wilderness, and St. Augustine of Canterbury preaching Christianity in England. These panels were carved by Messrs. Trollope & Sons. The panels are separated from one another by angle-posts, which are highly enriched with bases and canopies and figures of the Four Evangelists and of St. Athanasius, cut out of the solid, as are the canopies and figures on the pillars below.

The staircase, giving access to the pulpit, has at the angles large posts, moulded and with the ends carved into figures, the panels between being pierced with small traceried openings. The back-board, occupying the three small sides of the pulpit towards the wall, is divided at each angle by groups of three hexagonal shafts, the surfaces cut into diapers of hexagons and other figures. The four groups of shafts thus placed, and two which stand detached, support the great sound-board, which is thus sustained at six angles. The heads of the supporting shafts are connected by pierced tracery and crockets.

The sound-board is based on a figure of fourteen equal sides, but several of these are lost, the back being cut into by the piers carrying the chancel arch. The heads of the shafts carrying the canopy are connected by a slightly raised band, the space comprehended within the band being of the same size as the floor of the pulpit. Projecting beyond the band, the sound-board overhangs about 2 ft., making the total width across from side to side 10 ft. The underside is inlaid and polished.

Around the edge of the sound-board is a cornice carved with the following inscription, in riband letters, "Clama, necesses quasi tuba exalta vocem tuam et annuncia populo meo scelera eorum et domus Jacob peccata eorum." At the end, in a small riband, is the date of the execution of the work, with the names of the donor, the carver, and the architect. The cornice is surmounted by a very rich pierced cresting, with stout pinnacles at each angle, and from the level of this cornice springs the lofty canopy,—14 ft. from the nave floor to the top of the sound-board, and 40 ft. 8 in. more to the summit.

The plan of the canopy is octagonal. It commences with a solid drum, surrounded by a group of detached buttresses, which are joined to one another by carved foliage and tracery, the object of which is to ease off the transition from the flat line of the sound-board to the aspiring vertical line of the canopy work.

At a height of 19 ft. from the nave floor the angles resolve themselves into pillars enclosing an octagonal space, in which is a group, the Nativity. The tops of these pillars are joined by tracery, and above this springs a mass of tabernacle-work, tracery, and pinnacles. Over the heads of the group the pillars are joined with ribs and a large central boss, consisting of a star, within which is a crown of thorns surrounding a rose.

Above the tabernacle-work the size of the octagon is somewhat diminished, and the sides are filled in solid; but at a height of 27 ft. we find a second open space, similar in general details to the foregoing. In this is a second carved group of figures, the subject being the Crucifixion, with the Blessed Virgin Mary on one side of the cross, and St. John on the other. This is again surmounted by tabernacle work, differing in design from that below; and again, the octagon diminishes still more till we arrive at a third open space surrounded by pillars, and in which is a figure of our Lord ascending. Above this is more canopy-work, and, finally, a crocketed spire, terminating in a carved finial, which comes to within 6 in. or 8 in. of the roof of the church.

With the exception of the four panels already mentioned, the whole of the work has been executed by Mr. J. E. Knox, of Doris-street, Lambeth, who also carved the reredos. The work was designed by Mr. Somers Clarke, jun., of 6, Delahay-street, Great George-street.

THE KING'S SCHOOL, SHERBORNE.

THIS school is one of the earlier foundations of Edward VI., and occupied at first some small buildings erected partially on the sites of the Lady Chapel of the abbey and of the Chapel of St. Mary-le-bow attached to it. These original school buildings still exist, and are used as the dining-hall of the school-house, and for offices. The original effigy of the founder stands over the dais of the hall; gradually the school increased, and in more modern times the "Bell buildings" were added, with others built against the walls of the ambulatory of the choir, but it was not until under the headmastership of the Rev. H. D. Harper (now principal of Jesus College, Oxford) that the school assumed its present importance.

In 1853 the late Earl Digby presented to the governors of the school a block of buildings on the north side of the abbey church, then used as mills; they consisted of the ancient Abbot's Lodgings, the Abbot's Hall, the Guesten Hall, and a small portion of the dormitory building, forming parts of three sides of a quadrangle, of which the abbey church was the fourth. These buildings were placed in the hands of the late R. C. Carpenter, under whose direction they were carefully restored. The Guesten Hall became the new school-room, the Abbot's Hall was consecrated as a chapel, and the Abbot's Lodgings were converted into boys' studies. The lower story of the Guesten Hall was used as class-rooms with an open cloister under the chapel; portions of this cloister are of Norman date, the rest of the buildings are of the fifteenth century. Later, the school-house was erected, the chapel lengthened, and class-rooms built, under the late Mr. W. Slater, chiefly through the liberality of Mr. G. D. W. Digby, of Sherborne Castle.

As the school still continued to increase, and a new scheme of the Ecclesiastical Commissioners having come into operation, fresh enlargements had to be undertaken from Mr. R. Herbert Carpenter's designs, and they have been carried out under him and Mr. Benjamin Ingelow.

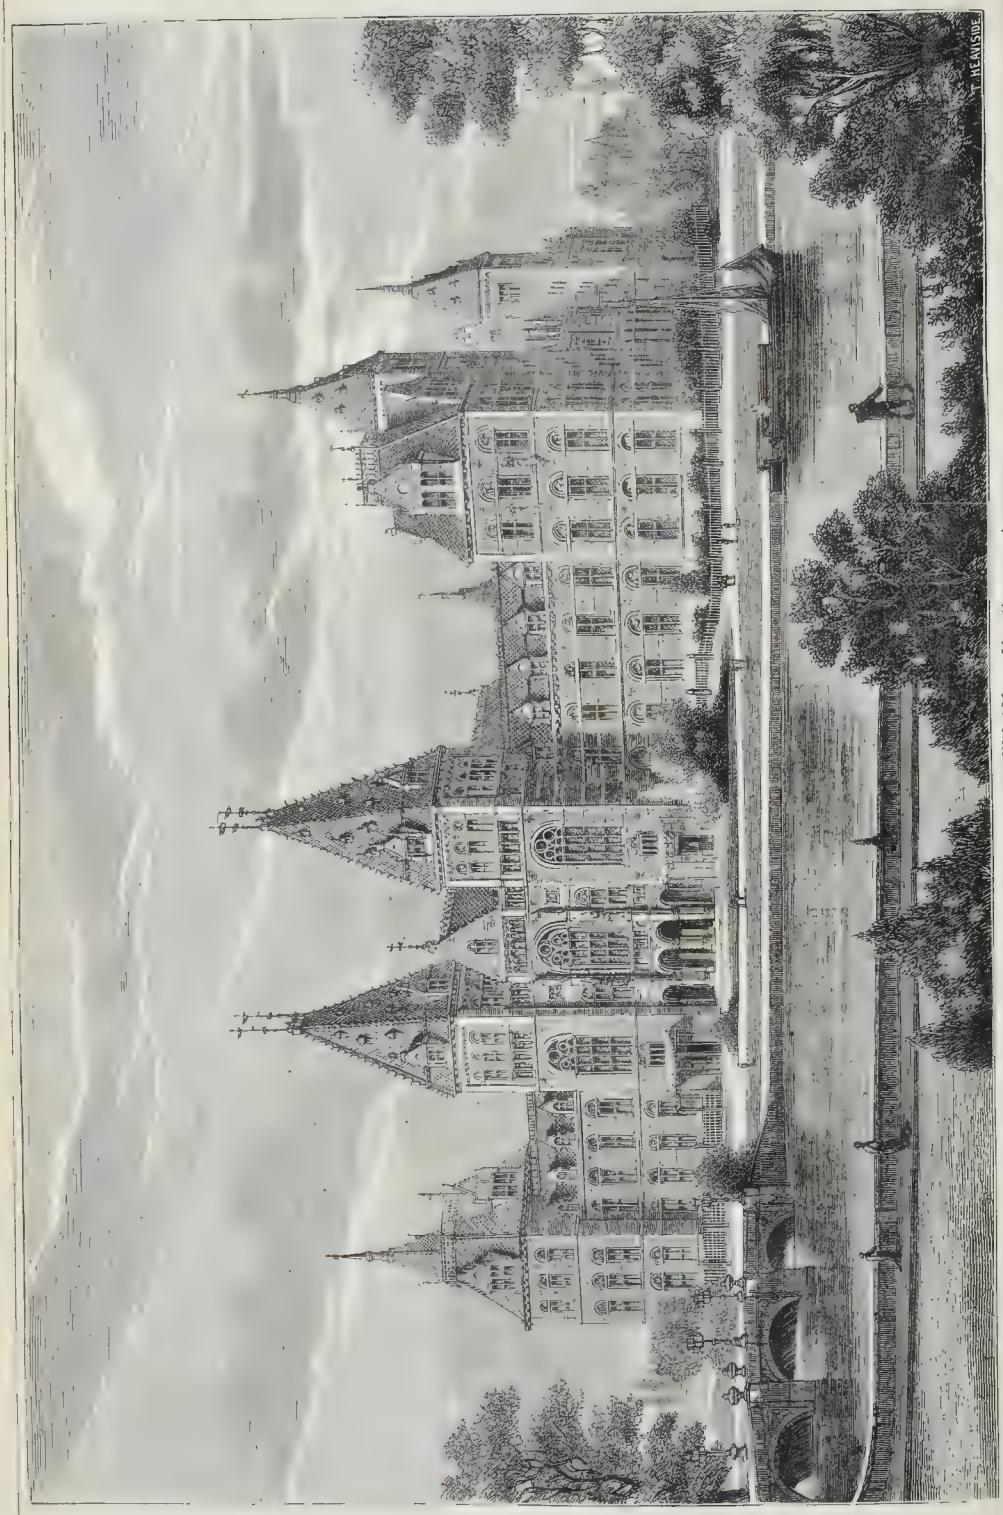
A new great schoolroom has been erected, 84 ft. by 28 ft., to which, hereafter, are to be added class-rooms at its northern end.

The question of the chapel has been anxiously considered, and alternative plans had been prepared for a new one on the north side of the new quadrangle, but eventually the plans were arranged by the Rev. H. D. Harper, with the architect, for adding an aisle to the existing chapel, with buttresses, &c., of such proportions that eventually the whole chapel might be raised, and, by the removal of the temporary arcade, the area of the aisle might be incorporated in one span with the body, so as to give a chapel of more imposing dimensions. The present addition to the chapel, as shown, was designed with this idea. The lower story is of equal height with the Norman substructure of the nave, but is designed with vaulting and openings to correspond with the superstructure.

The new reredos, with its sculpture, the master's and choir stalls, and the pavement have been placed as a memorial to Dr. Harper, who left the school just as the works were commenced, being succeeded by the Rev. E. M. Young, late of Harrow.

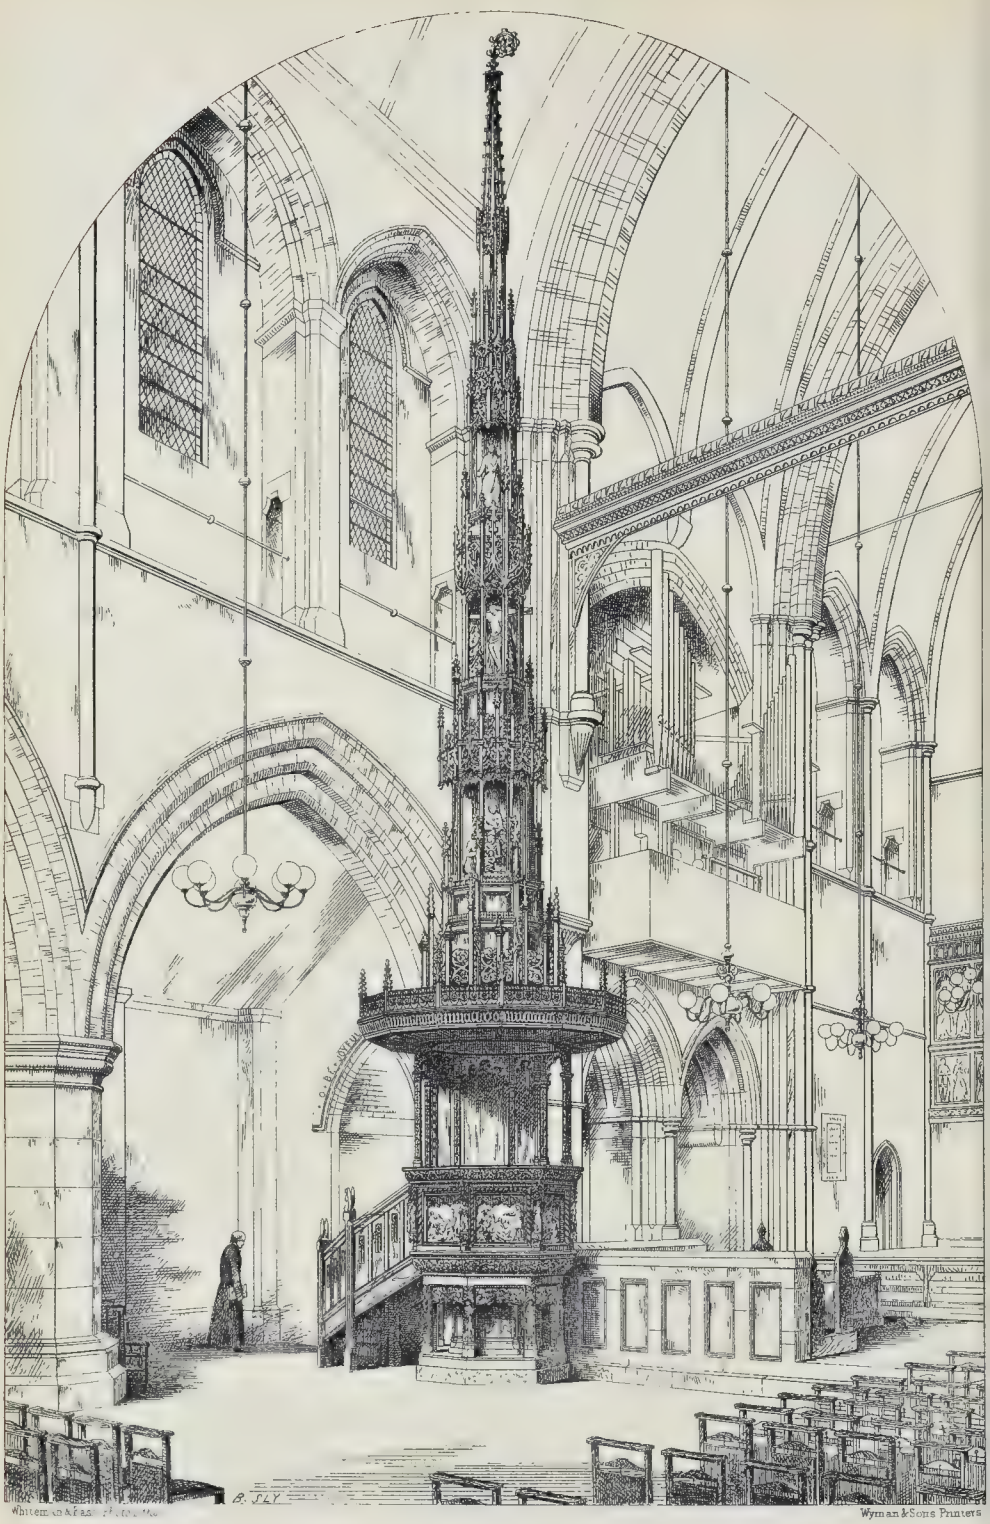
The connecting vaulted cloister between the schoolroom and the chapel are now in course of erection, and the old schoolroom is being converted into a school-library, with fittings of oak.

The general contractor for the works is Mr. Sealey, of Sherborne, Mr. Walker being clerk of the works.



The material used is local coursed stone, with dressings of Ham-hill stone, and the roofs are covered with the local stone slates.

The block of buildings on the left-hand of the view is the ancient Abbot's Lodgings, with his private entrance from the town (the staircase to the "solar" was in the semi-octagonal projection). Next is the chapel,—the ancient Abbot's Hall,—with the clearstory of the nave of the abbey church towering over it. Then there are the connecting cloister, and the new schoolroom on the right of the view.



HOUSE AT LANSDOWNE-ROAD, HOVE, BRIGHTON.

THIS illustration shows a house recently erected at Brighton for Mr. F. Algar. The walls are faced with patent waterproof red facing bricks, with cornices and dressings in red terra-cotta. The floors are bordered with parquetry, and the lower panes of windows are filled with stained glass. The house has been built by Mr. J. Barnes, of Brighton, from the design and under the superintendence of Mr. H. J. Lanchester, architect, of 3, Abchurch-yard, London.

The First Avenue Hotel, about to be erected on the north side of Holborn, will have its main frontage to that thoroughfare, and return frontages to Warwick-court and Brownlow-street. The property acquired includes the site of the Duke's Theatre, burnt down some time ago and not since rebuilt. The new building will occupy a superficial area extending to nearly an acre. The hotel is to contain nearly 400 rooms, and will be called the "First Avenue" Hotel, from the fact that it is intended to have an arcade or avenue running through the middle of the block.

HOUSE AT BRIGHTON FOR MR. F. ALGAR.— Mr. H. J. Lanchester, Architect.

THE NATIONAL MUSEUM, AMSTERDAM.—*Plan of Ground Floor.*

instead of *into* them, we have next to consider how to *maintain the purity of the air of the rooms we inhabit and defile* with our own breathing, our house warming and lighting, and cooking, &c. In this matter also, sanitary science has made many revelations of more or less gravity. The late Dr. Parkes has shown in great detail the various sources of impurity to which the air of enclosed spaces is subject, and the particular diseases to which such impurities give rise, under the title of "Ventilation,"—a term which he restricts "to the removal, by a stream of pure air, of the pulmonary and cutaneous exhalations of men, and of the products of the combustion of lights in ordinary dwellings; to which must be added, in hospitals, the additional effluvia which proceed from the persons and discharges of the sick. All other causes of impurity of air ought to be excluded by cleanliness, proper removal of solid and fluid excreta, and attention to the conditions of surrounding dwellings."

To expound the revelations of sanitary science by which the above impurities are detected, measured, and overcome, is my next intention; and, having regard to the mixed nature of my audience, I will do so in as popular a manner as possible.

It is usual to measure the impurity in the atmosphere by the proportion of carbonic acid it contains,—not because this is the only or even the chief cause of its unhealthiness, but because the presence of carbonic acid is indicative of the proportional existence of other impurities, viz., foul organic matter and moisture, and also because the amount of carbonic acid can be accurately measured, and therefore may be usefully taken as an index of impurity generally.

The average amount of carbonic acid in the air outside of the house is four parts in 10,000 parts; when it reaches six parts in 10,000 inside, the room begins to be stuffy. Dr. De Chaumont has shown that about 3,000 cubic feet of fresh air per person per hour are necessary to preserve the air quite fresh; practically, however, no more than 750 cubic feet per person per hour is attainable in this country without producing draughts.

As Dr. Corfield observes, the air in our houses is rendered impure in various ways, but chiefly by our respiration, and by the products of combustion that are allowed to escape into it from lights and fires. Thus the air that we expire contains a certain quantity of foul or putrescent organic matter. It is charged with moisture, and contains about five per cent. less oxygen, and nearly five per cent. more carbonic aid, than the air we inspire. Add to this that every foot of gas consumed is equal to the addition of one person's expiration, and the need of changing the air is quite obvious. This change of air can only be effected by the admission of fresh air and the concurrent abstraction of foul air. It is not enough to provide for the extraction of air without providing for its incoming, because the effort of natural forces seeking equilibrium will cause the air to be drawn through every crevice in doors and windows, and even through solid walls and floor, creating currents of air *en route* to the motive power, viz., the partial vacuum which the fire in the grate produces. Neither is it sufficient to provide for the admission of air if there are no means of outlet; and if the chimney-flue is closed it will not enter of itself at all, but will require to be forced into the room, by which process the occupants of the apartment will feel no more delightful sensation than is experienced by a descent in the diving-bell at the Polytechnic.

In ordinary houses, the chimney is a sufficient ventilator when associated with a means of feeding the chimney with a supply of air, to prevent its feeding itself by drawing from every crevice as aforementioned. To feed the fire directly, however, would probably prevent draughts, but it would decrease the warmth and leave the room unrefreshed by the change of fresh for expired air. Consequently it is obviously desirable to introduce the air in such a way that it may do all the good it can before it reaches the fire and is swallowed up by the chimney current.

Now, it has been proved by experiment that the ordinary current up the flue of a sitting-room fire-place is at the rate of from 3 to 6 cubic feet per second, or 300 cubic feet per minute, or 18,000 cubic feet per hour. Consequently, allowing 1,000 cubic feet of air per hour as [necessary to be extracted for each occupant of any chamber, obviously one sitting-room fire-place flue is a sufficient extractor for eighteen persons; if 3,000 cubic feet per hour be insisted on, as recommended by Dr. De Chaumont, then six persons are efficiently provided for by this means, which is all-sufficient for practical purposes in dwelling-houses, except in the reception-rooms on party nights, when a much larger volume of expired air will be required to be extracted, to make way for the equivalent of fresh air which it is necessary to introduce to keep up the interchange and to maintain the purity of the air generally. In winter this fresh air can be warmed in its passage.

The foregoing principles underlie the best of the mechanical appliances constructed for the ventilation of dwelling-houses. And proceeding upon these lines, Mr. Tobin has credit of reviving an old principle laid down by Mr. Whitehurst, F.R.S., and published in 1794, and of putting it into practical use most successfully at the Ophthalmic Ward of St. George's Hospital, which is a room about 20 ft. square by 14 ft. high. Mr. Tobin closed all extract ventilators except the open fireplace, which it is necessary to keep going, winter and summer, and day and night, to maintain the velocity of the upward current in the chimney, which was thus retained as the only and sufficient extractor. He next provided some eight or ten semi-circular zinc shafts, about 5 in. or 6 in. diameter, and 4 ft. or 5 ft. high, and fixed them at the four corners of the room, and equidistantly between them. These shafts are connected at the foot with horizontal channels leading through the thickness of the walls to the outer air, and form the fresh-air inlets,—one set of shafts being in communication with the channels leading to the outer wall gratings fixed on one side of the building, and one set of shafts communicating in a similar manner to gratings on the opposite side of the building. This was an after-thought, for when all the shafts communicated with the outer walls on one side of the building only, the room was either supplied with too little or too much air, just as the direction of the wind might happen to be towards or away from the said air inlet gratings. In this way the fresh air was introduced and the foul air extracted. No draught was felt by the patients, much less by myself and other professional visitors who congregated round the fire expecting such a result. In fact, the prophecy of Mr. Whitehurst, delivered a hundred years before, was fulfilled, thus: "Given, an air-duct about 3 ft. or 4 ft. long, and 5 in. or 6 in. diameter, fixed in either corner of the room most remote from the fire, and communicating with the external air, the incoming air will rise in a perpendicular direction to the ceiling, and being gradually diffused will soon acquire the temperature of the room. No person will be sensible of it, and the flame of a candle will not be in the least disturbed by it."

The Sanitary Engineering and Ventilating Company have done their best to improve upon this suggestion, and at the International Medical and Sanitary Exhibition at South Kensington, their various models were exhibited, showing how the blacks and dust may be intercepted in the passage of the outer air into the interior of the dwelling, and your own exhibition also furnishes examples.

The introduction of fresh air is specially provided for in a variety of stove-grates, and notably by Boyd's Hygiastic School Board stove; under the iron hearth, and through the gills at the back of the grate the fresh air passes, and is warmed in winter before it enters the room through the gratings in front of the stove, which are proportioned to the size of the room in which they are fixed for both warming and ventilating purposes.

Mr. Boyd does not consider the chimney a sufficient extractor, but always recommends extract ventilators to be used with his stoves, fixed at the foot of an air-flue built in the upper part of the wall opposite the stove, with not only a means of opening and cleansing the same, but also of heating the extract flue by a Bunsen gas-burner, as the means of rarefying the air in the shaft, and increasing the upward draught. If the objection is made that by forming extract flues you will materially increase the cost of the building by doubling the width of the chimney breasts and stacks, I answer, "No! If you are willing to do as I did, thirty years ago, at Mr. Boyd's suggestion, instead of making the withe or division between the flues of solid half-brickwork, make it a hollow flue by the introduction of cast-iron flue plates the thickness of a slate, leaving a clear 4 in. by 9 in. or 14 in., as the case may be, for a ventilating flue warmed on either side by the smoke-flues between which it is situated, occupying no more space than the ordinary flue-withe, and delivering into the open air 3 ft. below the smoke-flues through louvred openings.

But sanitary science teaches us to regard ventilation as something more than this. It has revealed to us that ventilation cannot be rightly studied and practised without due consideration of the mode of heating and lighting intended to be adopted in the room to be ventilated. Indeed, the temperature of the air within a room and without it, being different in density, in proportion that either is hotter or colder than the other, is one cause of the pressure of one atmosphere against another in search of that equilibrium which nature is ever seeking, and never finding for any length of time together. The whistling wind rustling through the woods and forests bloweth where it listeth: we hear the sound of it, but cannot tell precisely whence it cometh or whither it goeth, until we have traced to its source the provocative cause of its movement, which will be found to arise from the variations in humidity, temperature, and consequent density and pressure of the heavier against the lighter and brighter atmospheres, with which the former impinges upon the latter. Thus the draughts in a room are the result of the pressure of the cold air of the street or passage in its struggle to get to the warm air of the room, and particularly that part of it from which the heat is generated and projected.

When two rooms are of the same temperature, the air is stagnant; that is to say, no movement of the air from one to the other will take place by the opening of a means of communication between them. It is obvious, therefore, that if the whole of the interior of a house were equally warmed without the provision of inlets for fresh and outlets for foul air, there would be no change of air from one part of the house to another. But each room might be separately lighted, warmed, and ventilated by inlets and outlets, and yet the same temperature might be maintained, but with this difference, that there would be no stagnation, but pure fresh air, warmed as it entered for free inspiration, and withdrawn as by expiration or combustion it became impure. In the ventilation and warming of the house, the hall and staircase should not be forgotten. The best salvation from the wasteful consumption of fuel is the withdrawal of the cause of the draughtiness of rooms when the door is opened, arising from the difference in temperature between the sitting-room and the hall, by the introduction of a good hall fire or other system of warming the entrance-hall and staircase.

With reference to the lighting of rooms, of course the softest and most agreeable method is by wax candles, but the cheapness and brilliancy of gas, and its easy application has led to its general adoption, regardless of the sanitary consequences. For as Dr. Corfield observes in his Cantor lectures, "Candles, lamps, and gas all help to render the air impure."

"It is calculated that two sperm candles, or one good oil lamp, render the air about as impure as one man's respiration does, whereas one gas-burner will consume as much oxygen and give out as much carbonic acid as five or six men, or even more. This is why it is commonly considered that gas is more injurious than lamps and candles, and so it is, when the quantities of light are not compared; but with the same quantity of light, gas renders the air of a room less impure than either lamps or candles." Common sense at once suggests that the products of combustion should be carried away, and the heat generated by the process should be utilised to expedite its removal, and several manufacturers have turned their attention to this desirable end, and at the International Medical and Sanitary Exhibition, and at your own exhibition in this town of Eastbourne, examples may be found of many means to attain this end. Strode's sun-burners, Benham's globe light, Faraday's pendants, and many more appliances, all seek to give practical application to the principles above referred to. But we are fast arriving at the best solution of this difficulty through the agency of electricity. The sanitary side of this new lighting power is to us the most interesting. By the Lane-Fox and Swan incandescent lights, unequalled brilliancy, steadiness, and continuity of light are capable of being maintained, and this all pro-

duced within a vacuum formed within the globe of glass in which the light is produced; and consequently, by the use of these lights (which are becoming more common every day and will soon supersede gas altogether), no heat is generated, no dirt is caused, and no products of combustion mingle with the air of the room, from which no provision needs to be made in its ventilation for this system of lighting, which, as hereinbefore explained, is so necessary in the case of other lights.

This brief review of the Revelations of Sanitary Science would not be complete without a few words on heating.

The natural process by which the temperature of the air is raised is either by radiation or conduction. Conduction, or rather conducted heat, is the warmth given off to the air by heated surfaces brought into immediate contact therewith. Such heat in the ordinary fire-place is carried up the chimney, and the systems in use for generating it are known as hot-air stoves or flues, hot water carried in cast-iron pipes at low pressure, or in wrought iron pipes at high pressure, and steam pipe apparatus.

Radiated heat is like that of the sun, which passes through the air as light without heating it, into the earth or any intervening substance, from which the heat is given off gradually to the atmosphere, creating the difference between sun and shade temperature. Thus it is that the conducted heat of an open fire goes up the chimney, as I have said, and about a sixth part only is radiated into the room, passing through the air without sensibly heating it, but warming the first obstacle to its progress, such as the inclosing walls and furniture, by which the radiated heat is given off to the air of the room, raising its temperature as required. It cannot be called an economical mode of heating, being but one-sixth of the means to the end; but it is the most enjoyable and the most healthy. All the products of combustion pass up the chimney, and draw after them the impurities and denser air of the room lying lowest, while the vivifying rays of the crackling fire heat without scorching the surfaces that warm the air of the room insensibly.

The primary but not the exclusive object in the improvement of an open fire stove must obviously be the increase of its radiating power by reflection from heated polished surfaces in close contact with the fire, and this is done by many of the best stoves,—one of the latest of which is Messrs. Comyn, Ching, & Co.'s new stove called "The Paramount." In this case the fire-basket or grate is quite disconnected from the brickwork surrounding it, and equally so from the metal case, excepting at the point of contact with the bracket which sustains the circular grate. Thus the fire is enabled to radiate as from a centre all round. The rays of heat emitted from the back and sides of the fire-basket, impinging on the metal reflector of the back and sides, are reflected forward into the room and utilised, instead of being lost as before.

The secondary object, economy in fuel, is attained by the first, and by bringing in conducted heat from chambers provided at the back of the grate; and the third is the consumption of smoke. This has occupied a great deal of attention of late, with the object of purifying the air of blacks and the reduction of London fogs. An exhibition of stoves designed with this object will take place in London in October, and we shall soon see with what result.

In the meantime, the "Wonderful Grate" exhibited by Messrs. Smith & Co., at the London Sanitary Exhibition, accomplishes a great deal in this direction. It is an open fire-grate, and yet consumes its own smoke. It burns anthracite coal. It is fed with fuel in the morning, and needs no attention till night, until the fuel is consumed. It requires no stoking, yet has always a clear, bright, red fire, the radiating power of which is considerable. Then there is Dr. Siemens's grate, which is an attempt to combine gas with anthracite coal, and a host of others.

The history of the heating and ventilation of the British House of Commons, both old and new, is perhaps as instructive a lesson in this branch of sanitary science as any which could be named. Sir Christopher Wren, Captain Cook, Sir Humphrey Davy, the Marquis de Chabannes, and many others tried their hand at the old building. Dr. Reid, Mr. Gurney, and the present Dr. Percy, have had their way with the new. However, it is not my intention to refer to public buildings now, but only to draw attention to the importance of the principles laid down by sanitary science which are applicable to all householders, and the revelations of which I have now traced as they have influenced house-drainage and the ventilation of the same, house warming and lighting, and the ventilation of the rooms in which we live and move and have our being.

If I have made no new revelations, I have at least endeavoured to popularise the old, and I think we may look forward with confidence, as the result of such exhibitions as that which you have inaugurated in this town, that their need will become less and less as time advances, knowledge increases, and the evidence of the value of these revelations accumulates. It is a work of "sweetness and light." It aims to realise that which hitherto has existed more in the imagination of the poet than in fact,—

"Home, *sweet* home."

THE BRITISH ARCHÆOLOGICAL ASSOCIATION AT MALVERN.*

FOLLOWING the reading of Mr. Hopkins's paper on the history and architecture of the Priory Church at Malvern,

Mr. Loftus Brock, F.S.A., pointed out the analogy in date and construction between Malvern and Gloucester churches. The church of Gloucester was dedicated in 1100, and the tower was built about 1450. The capitals of the Norman pillars of Gloucester agreed in the smallest details with those of Malvern. He knew of no large Norman church without the apse. It was from the earliest times a sign of Latin influence. The little Roman church unearthed at Canterbury had the apse. The apse was not found in the old Irish churches and many of the Saxon churches. The fact that Malvern Church was dedicated in 1239 had puzzled some writers. Matthew Paris threw light on the subject, showing that it was in obedience to constitutions made in London in 1237 by the Papal legate. The inference was that many churches had remained unconsecrated for a long time; and it was probable that many old churches had never been consecrated at all.

There was an excursion to Ripple, Bredon, Overbury, and Tewkesbury on the second day (Tuesday, August 23rd), when more than 100 members and visitors journeyed by special train to Ripple. On the way to the parish church, the party halted at the village cross, which is of oolite, and very much resembles the cross in Malvern churchyard. Beneath the cross still stand the stocks. At the church, the rector, Mr. Holmes, was in waiting, and gave from the pulpit a little history of the church. There was a monastery at Ripple before the year 800, and probably an older building stood on the site of the present church, which was largely of the thirteenth century. Some very curious oak carvings, thought to be the misereres of some collegiate church, attracted much notice. It is believed that, as they were once in the hands of Bishop Hough, they came from Worcester. Most of them represented agricultural pursuits, such as binding corn or driving animals. Another showed a couple of monks cooking.

A heavy storm burst over the valley of the Severn as the travellers set out in brakes from Ripple. Having passed through Twyning and Twyning Fleet, they forded the Avon by the ferry-boat, and soon reached Bredon Church, which afforded welcome shelter from the drenching rain. Mr. Adye, curate in charge, read a short paper, giving an account of the history of the church, referring, among other things, to the residence in Bredon of John Prideaux, bishop of Worcester. In the churchyard was noticed a singular example of a high tomb with a coped top, but to whom it was raised is not known. A so-called "parvise," over the Norman porch on the north side of the church, was pointed out, but Sir James A. Picton, F.S.A., explained that there was no authority for the term "parvise," as far as he had been able to trace, and he therefore considered it only a fanciful one, and of little or no meaning. Mr. Loftus Brock gave an interesting little dissertation on the church. He thought it a beautiful specimen of the architecture of the early part of the thirteenth century. The three entrances were all round-headed, with the zig-zag ornament; but the mouldings were the same as those of some of the internal arches. The plan was Norman, with a tower between the nave and chancel. One of the large windows was Decorated, and another Perpendicular; but the district was one which afforded few examples of the Decorated. The sepulchral slab, placed in an erect position in the south chancel wall, was very remarkable. It represented our Lord on the cross, and probably the husband and wife who founded the chantry chapel. The recessed canopy on the other side of the chancel might possibly have been intended for an Easter sepulchre. The monument was decorated with the ball-flower ornament, which was very prevalent in the district. The steps were paved with encaustic tiles, bearing the armorial bearings of the Beauchamp and other families. A peculiarity of the church was its great ascent from west to east. In the chantry chapel one of the monuments testified to the old form of heart burial. The monument to the memory of Giles Reed, sheriff of Worcester, was one of much magnificence. The church was a "peculiar," not being under the visitation of any bishop. After looking at the church, several of the party went to inspect the celebrated tithe-barn, which remains to this day a splendid example of the skill of the carpenters of the fourteenth century.

The unfavourable weather compelled the abandonment of a visit to Bredon camp, and the next halting-place was Overbury Church. It is rarely that the archæologist comes upon so fine an example of the Norman village church. The massive pillars of the nave, so low that the hand can reach the top of them, remain in all their completeness; but the small circular-headed windows above, which at one time lighted the nave, have now become an internal feature, owing to the rebuilding of the aisles in later times. An Early English chancel was also added in later times. Mr. Glynn descanted on a few of the features of the church. The font caused some little speculation. It was admitted to be of the very earliest type; and some present, judging especially by the representation of a church in the hands of a saint, pronounced it to be Saxon. The party next drove on to Tewkesbury, where they partook of luncheon at the Swan Hotel. During the afternoon the Abbey Church was visited, and a paper, by the Rev. Hemming Robeson, the vicar, was read by Mr. Sergeant.

Mr. Robeson's paper, after briefly referring to the origin of the name "Tewkesbury," said it was probable that there was an Anglo-Saxon church there in the eighth century, and then, passing on to the Norman period, he pointed out in the choir the Fitz-Hamon, or, as it was called, the Founders' Chapel, on the north side, which carried them back to the period following the Norman Conquest (1066). At that period two notable figures rose up before them,—that of Fitz-Hamon, a nephew by marriage of the Conqueror, the first founder of the present abbey, and his son in-law Robert Fitz-Roy, Earl of Gloucester, a left-handed son of Henry I. These two figures, after some twenty-two generations had passed, speak to us, if he might say so, even to-day from the Norman pillars of the church, from the transepts and great central tower which surmount the present abbey. It was in the main still their church. The first Earl of Gloucester was called the second great founder of the abbey. In the lifetime of his eldest son, Earl William, a destructive fire destroyed (in 1178) the monastic buildings, and left its traces also on the south wall of the church. It was said King John resided for a time at Tewkesbury in the year of his coronation, 1200. At that time the abbey came under the interdiction of Pope Innocent III. Abbot Alan was afterwards translated from the Priory of Canterbury to preside over this abbey in 1187. His tomb was on the left of the vestry door, and his coffin-lid bore the inscription, "Alanus Dominus Abbas." In 1795 the coffin was opened, and the abbot was seen lying in his vestments, with the cross and chalice, as he had been laid there 600 years before. The next family that became lords of Tewkesbury was that of the De Clares, of whom Mr. Robeson gave a history, and pointed out their burial-place. During the lordship of the De Clares, however, no considerable additions were made to the fabric of the abbey, though he must not pass over the two beautiful chapels in the north transept (now united by an arch of the fourteenth century) which belonged to the thirteenth century,—about 1230. What he might call the first great change from the Norman work of the Fitz-Hamons belonged to the time of the Despencers, into whose hands the lordship of Tewkesbury passed through the

* See p. 265, *ante*.

marriage of Eleanor, eldest sister of the last De Clare, who was slain at Bannockburn, with Hugh Despencer the younger, in 1321. Mr. Robeson then glanced at the history of each of the Despencers, whose monuments formed the most striking architectural beauties of the choir of the church. Sir Gilbert Scott had described the alterations which took place at that period, which now consisted nearly of the reconstruction of the whole eastern arm of the church from the Norman into the Decorated architecture of the fourteenth century. Sir Gilbert added that it was probably carried out at the cost of the Despencers. The brasses recording their respective resting-places were, therefore, he thought, hardly necessary to perpetuate their memory. It was enough to say, "*Cive virtute*." The several Despencer monuments were then all pointed out and described. What was generally known as the Warwick chapel, he said, ought rather to be called the Beauchamp chapel. It was erected in 1422 by the Lady Isabel, sister of the last Lord Despencer, in memory of her first husband, Richard Beauchamp, Earl of Abergavenny, who fought at Agincourt. On the death of her husband at the siege of Meaux, in 1421, the young widow raised to his memory the sumptuous chantry chapel, and took for her second husband another Richard Beauchamp, the well-known Earl of Warwick. The rev. gentleman concluded with some remarks on the recent restoration.

It had been intended that the site of the battle-field should be visited, but this was abandoned, owing to the badness of the weather.

At the evening meeting, held in the Council Room of Malvern College, Mr. J. Tom Burgess, F.S.A., delivered an address on "The Ancient Encampments of the Malverns," which was illustrated by a valuable collection of plans by Mr. H. H. Lines, of Worcester, and Sir Henry Dryden. Mr. Burgess said a few years ago it was his lot to read a paper at the Wolverhampton Congress of the Association on the remarkable series of earthworks then recently found on the northern bank of the river Avon; and he had occasion to point out how like in several respects these earthworks were to those extending along the Cotswolds into Gloucestershire. These two chains of earthworks represented two different races. He had now undertaken to point out the particular features of the earthworks visible from the Malvern Hills. Having spoken of the earthworks at Meon Hill and on Bredon, he referred to some remains apparently indicating a large settlement on the North Hill, at Malvern, and to those of an ancient village above St. Ann's Well. As they approached the great mid-range of the Malverns, they found themselves at the foot of a conical hill, the Herefordshire Beacon, which was terraced and cut into forms most unusual. When they had scaled the ramparts, they were in the midst of a ditch wide enough to allow a chariot to pass along it; and going along, they came to the central mound, with a thick vallum and low ditch. Looking round, the eye beheld one of the most charming panoramas that could possibly be found. The next thing that struck one, next to the vastness of the work, was that it appeared to have been erected at very different times. The central mound was oval, it ran in a peculiar direction, and originally had only one entrance into it. About two years ago it was resolved to find, if possible, what the mound contained; and a variety of bones of domestic animals, and pieces of pottery of the Romano-British period, were found. A midden was opened containing some burnt pottery. A peculiar piece of slate, drilled with a hole, was also found. It had been called a burnisher; but he believed that it was simply a sinker for a fishing-line. An iron arrow-head was found; but, with these exceptions, there were no indications of the life of the original inhabitants to show that they did more than eat and drink. The whole of the hill was encircled by covered fosse-ways, along which people could pass without being observed from the outside. About a mile and a half further along the range, on the Midsummer Hill, there were entrenchments of an entirely different kind. At the entrance there were sunk pits, evidently for guarding the sentinels. Passing along the rampart, one came to a lower series of entrenchments, of a very remarkable character. This camp he took to be the oldest of the two camps. It appeared to have been one of the old settlements of the tribe. Mr. Burgess referred to the great struggle between the Ancient Britons and the Romans, of which the neighbourhood was the scene; but expressed his opinion that the Herefordshire Beacon had been occupied by more than one people. It was probably held by the Welsh up to about 950, when Athelstan took it. To that period he should assign the crown found in the neighbourhood in the seventeenth century.

Mr. Brock read a letter he had received from Mr. M. H. Bloxam, F.S.A., of Rugby, in which he expressed his opinion that the ancient British camps in Worcestershire were the fortresses of the Silures, whose eastern boundary he took to be the Severn. The contest of the nine years' war between the Romans and Caractacus it might be fairly assumed was on this ground. He knew of no one better qualified to investigate these earthworks than Mr. Burgess. Mr. Brock added that they could not but be struck with the general analogy between the Malvern camps and two great camps at opposite extremities of England—Sisbury and Castle Hill, Huddersfield. In one of the great camps, which Mr. Burgess had so graphically described, there was—first, the fortress proper; second, the hut dwellings; and third, the part for cattle. These fortresses were not camps in the proper sense, but towns. Through the labours of Mr. Burgess, Mr. Roach Smith, and other gentlemen, they were beginning to see the real nature of the camps, and to learn that they were not thrown up hurriedly or hastily.

Mr. G. R. Wright, F.S.A., referring to the finding of the crown, pointed out the necessity for an alteration in the law of treasure trove.

Mr. J. Nott then read a paper on "The Glass of the Priory Church." He said that most of the windows were but mere fragmentary remains. Some of the glass was as clear and beautiful as when it was first painted. The dates of the windows were fourteenth, fifteenth, and sixteenth centuries. That in St. Anne's Chapel treated of "The Creation" and "Fall of Man," in twelve pictures; representing the Almighty forming the universe out of chaos; the creation of the moon and the stars, plants, fowls, beasts, and trees; Adam asleep, and the Deity taking a rib to create woman; God leading Adam and Eve into Paradise, the temptation, the hiding among the trees of the garden, the expulsion from the garden, Adam tilling the ground, and Eve nursing the infant Cain. Another represented incidents in the history of Noah and the Ark, Babel, and the marriage of Abel. In the south window were God appearing to Abraham, Abraham taking Sarah to wife, the casting out of Hagar, the journeying to Mount Moriah, and Isaac sending Esau for venison. The east window (Perpendicular) represented the Annunciation, the Twelve Apostles, scenes from our Lord's life and passion, our Lord's triumphal entry into Jerusalem, the Last Supper, the Betrayal, the Scourging of Jesus, Christ raised on the Cross, and the Descent from the Cross. In the north window can be traced the Trinity crowning the Virgin Mary; there is also represented the offering of the Magi, Adam and Eve praying in the midst of infernal spirits, and our Saviour leading them out of Hell; the turning of the water into wine; and other pictures and portraits had once had place. In the clearstory window of the choir was the only record left of the Legend of St. Werstan. Description would not, however, fairly depict them, they must be carefully examined to be appreciated.

Mr. Johnson Cope said that in these windows of the olden time there was a gem-like appearance and soberness of colouring which were very charming.

Mr. Brock referred to the great loss of painted glass which had taken place in the past, owing to carelessness. All they knew about St. Werstan was from the four little pictures in glass in Malvern Abbey Church. He should ascribe the glass to English artists.

On the third day (Wednesday, the 24th) excursionists to Bosbury, Ledbury, Much Marcle, and Kempley were favoured with better weather than prevailed on the previous day. Starting by train for Ledbury, carriages were taken there, and the party proceeded to Bosbury, where the Early English church and its detached tower were examined. The detached tower is a curious feature in the church architecture of Herefordshire. The Rev. S. Bentley read a paper at the church. Some vestiges of the old palace of the bishops of Hereford were inspected. The party then returned to Ledbury, where they arrived shortly before noon. One of the first objects that attracts the attention of a stranger in Ledbury is the timbered Market-house. As Herefordshire is peculiar for its detached church towers, so again it can boast of its peculiar town-halls or market-houses, either as existing or as preserved in sketches. Two of the most beautiful—those of Hereford and Leominster—have disappeared within the last half-century. Ledbury Market-house, elevated on its sixteen oak pillars, remains. The church was entered through the fine Norman doorway. The building presents points of much interest to the antiquary. It was originally a Norman structure of great size and beauty. During seven or eight centuries, however, it has undergone great transformations. The round openings of the chancel, which at first doubtless were intended to let in light, have now, by the raising of the aisles, become an internal feature. In this respect the chancel of Ledbury is like the little nave of Overbury, where the small round-headed windows now look into the aisles. St. Catherine's Chapel is richly decorated with the ball-flower ornament. The monuments of the church are very beautiful. A modern altar-tomb, with a figure of a child, by Thorneycroft, was much admired. The Rev. J. Jackson read a paper on the history and architecture of the church. Near the church was a narrow lane called Cabbage-lane, which was a corruption of the word Capuchin, indicating, perhaps, that at an early period of English history a body of Capuchin monks were established at Ledbury. If any remains of an older church than the present one still existed, they were to be found in the hagioscope on the north side of the chancel. Shortly after the Conquest a Norman church existed on this spot, as was still evidenced by the Norman doorway, the chancel arch, and other remains. It was curious that the east and west sides of the chancel arch did not correspond. In the early part of the thirteenth century the Norman side aisles were taken down, and in the early part of the fourteenth century the south arcade was taken down. It was also in the fourteenth century that the beautiful chapel of St. Catherine was built. St. Catherine was a religious woman who in the time of Edward II. settled at Ledbury. The lower part of the tower, which had always been separate from the church, was of Early English character.

Mr. Brock said that it was not improbable that Ledbury Church was a school of architecture to the district in which it was placed. It was a very unusual thing for a Norman church to exist of so great a length. The capitals of the arches of the chancel exactly agreed with those of Overbury Church. He attributed the whole of the Norman work to the close of the twelfth century. There was a fragment of an older church at the back of one of the piers, as was shown by the jointings.

Luncheon was partaken of at the Feathers Hotel, after which the party drove to Much Marcle Church, which was described by Mr. G. H. Piper. Kempley was next visited, and its interesting wall-paintings, discovered a few years since, were described by the Rev. J. Crowley Weaver, the rector. Attention was called by some of the visitors to the dangerous state of the tower. The party returned from Ledbury by train to Malvern.

At the evening meeting in Malvern, Mr. Wright read a paper on "The alleged Assassination of Prince Edward after the Battle of Tewkesbury."

The Rev. Canon Winnington-Ingram followed with a paper on "The Ecclesiastical State of the Diocese of Worcester during the Episcopate of John Carpenter" (1444-76).

On the fourth day (Thursday, the 25th), specimens of ancient domestic architecture at Birtsmorton Court, Payne's Place, and Severn End were visited. The weather was, as on Tuesday, wet and cheerless. Birtsmorton Court and Church were described by Mr. W. S. Symonds and Mr. Loftus Brock, Payne's Place by the Rev. J. M. Guilding, and Severn End by the Rev. T. W. Wood. Severn End, said Mr. Wood, assumed its present form in the days of Sir Nicholas Lechmere, a nephew of Sir Thomas Overbury. Sir Nicholas was born in 1613, and called to the bar in 1641. In 1656 he found it necessary to pull down and rebuild part of the house; in 1658 he finished the garden wall, and in 1661 he built himself a study in the garden. Severn End was sold many years ago to a Leicestershire gentleman, but was recovered by the late baronet. For more than 700 years the family lived on that spot; and although the present owner did not reside there permanently, he delighted in keeping up the old place where his ancestors lived and died.

At the evening meeting in Malvern, Mr. C. H. Compton read a paper on "The Antiquity of the Game of Golf," and the Rev. W. S. Lach-Smyrna one on "The Records of Municipal Corporations," with special reference to Cornish boroughs.

On the fifth day (Friday, the 26th) the members visited Kidderminster, where they were received in the council-chamber of the town-hall by the Mayor (Mr. H. R. Willis). Mr. J. Brinton, M.P., spoke of the interest with which the visit of the Society to Kidderminster was regarded, and said it was a fortuitous incident that several old charters belonging to the town, which had for a long time been missing, were found on the previous evening. He said that Kidderminster, anciently written Chiderminster, was supposed to owe its name either to the position of its church standing on the brow of a hill, with the water flowing beneath, or what appeared more reasonable, from the Saxon Earl Cynehorr, who received land here from Ethelbald, king of the South Angles, A.D. 716 to 757. When Domesday-book was compiled, Chidermiuster was held by William the Conqueror, along with sixteen berewicks, or corn-farms, most of the names of which could still be traced in the locality. Henry III. stayed in the town in 1233. It afterwards passed into the possession of the Beauchamp family, and then to the Foleys, and afterwards to the Ward family. The poet Waller acquired portion of the manor by purchase in Charles I.'s time. After some comments had been made by the visitors on the "loving cup," the charters, and various old documents, thanks were voted to the Mayor and Corporation, and the party visited an old crypt at the Fleece Inn, and thence went to the New Meeting, where they saw the pulpit in which Baxter preached in Kidderminster. They next went to the parish church, and in the chantry adjoining an interesting address as to the objects of antiquarian interest connected with the ancient fabric was delivered by the Vicar (the Rev. T. L. Claughton). The church was then inspected, and the party afterwards returned to the town-hall, where vehicles were awaiting to convey them to Wars Hill, Ribbesford Church, Arley Kings, and the Redstone Rock. They afterwards visited Moor Hall, where they were entertained by Mr. Brinton.

[By a misprint, the Guesten Hall, at Worcester, was last week erroneously spoken of as the "Gulston" Hall.]

THREE CITY GUILDS.

PAINTERS, PLUMBERS, AND FOUNDERS.

THE City Guilds Commission of 1834-37 brought together in their report a great amount of interesting information relating to the City Guilds and the duties and privileges which pertained to them in ancient times. A writer in the *City Press* has called attention to the subject, which now derives fresh interest from the efforts being made by some of the Guilds in furtherance of technical education and excellence of workmanship.

The *Painters'* or Painter Stainers' Company could, and still (in 1837) occasionally did, proceed against painters not free of the company practising the mystery in the City and liberties. For a considerable period the powers conferred by the charters were considered as extending not merely to the trade, but to the higher branches of the art. This fact appeared very clearly, not only from the language of the by-laws, but also from the names recorded in the books of the company. Verrio, Sir Godfrey Kneller, and many of the principal portrait-painters of the seventeenth and eighteenth centuries, were members of the company. Even Sir Joshua Reynolds thought it expedient to enrol himself as a Painter Stainer. For some time anterior to the date of the inquiry, however, the company had considered themselves as having control only over house-painters. Nor were even those contracted rights rigidly enforced. The City authorities had not given, it was testified, much assistance, even when they were trying to enforce their own Acts of Common Council. The clerk to the company had repeatedly given notice to the Chamberlain of non-freemen working as painters within the City, but no proceedings had been taken against them. In 1832 the contractor employed by the Common Council for painting the Mansion House was not a freeman of the company, or even of the City, and many of the workmen employed by or under the contractor were also non-freemen. In this case the clerk of the company gave notice of the facts of the case to the General Purposes Committee of the Common Council, but they took no notice of his communication. The contractor afterwards became a freeman of the company. We may add to this that a great deal of interesting information about this company is to be found in a little book written two or three years ago by our esteemed friend Mr. J. G. Crace, then Master of the company.

The *Plumbers* had retained an important and (in every sense but the pecuniary) a valuable privilege. They had not abandoned, but only fitfully exercised, the power of inspecting and searching houses, shops, and warehouses, and other places where the art or trade of a plumber was carried on in the City and within seven miles of it. This voluntarily-relinquished power applied to "workmanship, weights, beams, scales, and all other things whatsoever in any manner concerning the said art and mystery, and to see as to the buying lead of suspected persons, and to fine such persons as they shall find in default." But in an important department of their vocation the Plumbers still retained and exercised—and very much to the public advantage—their ancient authority. By their charter no person was to make, anneal, or sell any solder unless the same should be first assayed and found to be true. When required by any freeman of the company, the beadle attended at his shop and superintended the making of solder, which being all made and cast in bar, and the solder having been assayed by the beadle, the master and wardens then attended at the shop, and sealed the solder with the seal of the company, as directed by the charter. The assay consisted in ascertaining the due proportion of the metals employed, and whether they were mixed at the proper temperature, upon which much of the goodness of the solder depends. Sometimes six or more assays were taken before the beadle was satisfied with the alloy. The stamp, being a certificate that the article had been duly prepared, materially increased its vendibility and value. Foreign orders were given for it by the name of "sealed solder," and it was in special request in the East and West Indies, in France, and Austria. It was preferred throughout England, and little solder was made or sold except that sealed by the Plumbers' Company. The beadle, the report stated, was paid for his time and trouble, but the company exacted no fee for their seal. They only sealed for freemen of the guild. [The company did attempt, in 1832, to enforce their by-laws, but they were so "strictly construed" that it was found that practically they could not be enforced.]

The *Founders* possessed and still exercised functions similar to those of the Plumbers. To them was entrusted the "sizing and marking" of all manner of brass weights made or wrought within the City of London, or within three miles' compass thereof, or which should be sold or kept for sale within the said compass, together with the view and search of all brass weights and brass and copper goods whatsoever within such compass. These weights were all to be brought to the Hall to be sized and marked. All deceitful weights were destroyed. Witnesses on behalf of the company made the important statement that notwithstanding their jurisdiction only extended to the City of London and a limited radius round it, the weights stamped at their hall were generally circulated and used throughout the United Kingdom; and this had been the case for more than two centuries. [It may be added that weights intended for the colonies, and especially for India, are frequently stamped at Founders' Hall, owing to the extra care bestowed in "sizing." About 20,000 weights are stamped per annum upon an average.]

Science and Art Department, South Kensington.—The following is a list of the candidates who have been successful in obtaining Royal exhibitions of 50*l.* per annum each for three years, and free admission to the course of instruction at the following institutions:—1. *The Normal School of Science and Royal School of Mines, South Kensington and Jermyn-street, London:*—Thomas Mather, 24, pattern-maker, Manchester; Alfred Sutton, 21, engine-fitter, Brighton; William H. Littleton, 17, student, Bristol. 2. *The Royal College of Science, Dublin:*—Arthur Whitwell, 19, ex-pupil teacher, Nottingham; Frederick J. Willis, 18, student, Bristol; Christopher J. Whittaker, 21, pattern-maker, Accrington.

THE FOOD QUESTION.

WE have been paying for our fine July by a stormy August. Sinister predictions are everywhere heard as to the wheat crops, which a month ago were full of such golden hope. Our annual demand for wheat is from 24,000,000 to 25,000,000 quarters. Our imports for the last three years have averaged 6,700,000 tons of common flour, while our exports have been only 31,000 tons. Our own wheat crop this year is estimated at 9,500,000 quarters by Mr. James Caird, who adds that if we can reckon on a foreign supply equal to that of last year, and at not much over the same price, we shall be safe. Our payments for the last three years for imported corn and flour were,—59,000,000*l.* sterling in 1878; 61,250,000*l.* sterling in 1879; and nearly 63,000,000*l.* sterling in 1880.

SUNDERLAND BOARD SCHOOL COMPETITION.

AT a special meeting of the members of the Sunderland School Board, there were present, Messrs. R. Cameron (chairman), J. Stokoe, P. Wood, J. Kirk, T. W. Backhouse, M. W. Parrington, and the Rev. W. A. Walton, to receive the report of the General Purposes Committee on the plans for Stansfield-street School, Monkwearmouth, to accommodate 1,300 children, at a cost of 7,000*l.* Upwards of fifty plans were received in competition for the premiums offered by the Board. After a close contest between "Workable" and "I Work to Win," the committee finally recommended that the first premium be awarded to the plan bearing the motto "Workable," by Messrs. Rounthwaite & Shields, of Sunderland; the second to "I Work to Win," by Mr. G. G. Hoskins, of Darlington; and the third to "Study," by Mr. F. Clark, of Darlington.

It was decided, on the suggestion of Mr Wood, to exhibit the successful plans to the public in a room adjoining the Liberal Club.

PATENT RECORD.*

ABRIDGMENTS OF SPECIFICATIONS

Published during the Week ending August 13, 1881.

3. E. Bull, Halifax. Floor-springs, or apparatus for closing doors.

A lever is connected to the bottom of the door, which stands on a socket joint. A chain is attached to the lever, the other end of which is connected to a spiral spring fixed underneath the floor. The chain passes between two friction-rollers. Jan. 1, 1881. Price 6d.

12. J. Craven, Wakefield. Drying and burning bricks, tiles, pottery, lime, cement, &c.

This has reference to that system in which the burning is effected by gas. In the centre of the kiln, between the two series of chambers, is the gas-main, with branch-pipes communicating with the chambers. At each side of the gas-generator is a chamber in which air is heated by the generator and is led to the burning chamber by flues which surround the gas-main and branch-pipes. The bricks, &c., are thus thoroughly dried by the hot air before the gas is turned on to burn them. Jan. 4, 1881. Price 8d.

46. E. F. Osborne, St. Paul, U.S.A. Steam and hot-water apparatus for supplying heat to and utilising, measuring, and regulating the same in dwelling-houses, &c.

This invention, which has thirty-two pages of specification and forty-eight clauses, illustrated by fifty figures in the drawings, is not capable of being condensed. Jan. 4, 1881. Price 1s. 8d.

112. J. Peer, Salford. Consuming smoke from fires.

The bottom of the firegrate is formed of bars of an I shape, so that when placed close together a number of passages for air are formed; which air is led behind the fireclay back of the grate, and through perforations formed in the same at the height of the top of the fire. These currents of air consume the smoke. (*Pro. Pro.*) Jan. 10, 1881. Price 2d.

Published during the Week ending August 20, 1881.

5,183. P. Bedeau, Paris. Manufacturing ornamental mouldings of carton-pierre, &c.

The mouldings are made of carton-pierre or other plastic material by circular moulding dies of electro-deposited metal. (*Pro. Pro.*) Dec. 11, 1880. Price 4d.

127. J. Stone, Ulverstone; T. Kirby, Barrow-in-Furness; and E. Phillips, Ulverstone. Revolving shutters.

The end of a roller is fitted with a chamber, which contains the lubricant, from which chamber a pipe is led to a hole in the end wall of the end, through which a small quantity of the lubricant escapes at each revolution. Friction-rollers working in helical or spiral grooves are also applied to the ends of the revolving shutter-shaft, to allow it to revolve with less friction. Jan. 11, 1881. Price 8d.

* Compiled by Hart & Co., patent agents, 28, New Bridge-street, E.C.

130. W. Martin, Manchester. Pail for water or other closets.

The pail is fitted with a short tube at the bottom to draw off the liquid. To the outer end of this a flexible tube is attached, which leads to a trapped opening in the sewer. A lid is provided to the pail, which has a rim of india-rubber on the under side to make an air-tight joint. (*Pro. Pro.*) Jan. 11, 1881. Price 2d.

137. J. Reffitt & W. Irwin, Leeds. Apparatus for withdrawing and returning the plugs of urinals, closets, &c.

Two hollow receivers are mounted on frame-work, which is hung in bearings. Water being admitted to one of them, it flows through a tube to the other, which, when filled, overbalances the frame-work, and this latter receiver descends, lifting the plug at the same time. It is then emptied by a syphon, and the action is reversed, when the filling operation is again performed. This action is also applicable to flushing with a syphon, which may be connected to the framework instead of the plug. Jan. 12, 1881. Price 6d.

148. J. Friborg, Store-street. Venetian blinds.

The laths are connected by tape ladders. Screws which have the same number of threads as there are laths are placed vertically in the frame on each side. The ends of the laths are placed in the threads of these screws, and when these are turned, the laths are raised or lowered singly. (*Pro. Pro.*) Jan. 12, 1881. Price 2d.

158. L. A. Groth, Finsbury-pavement. Producing architectural ornaments in hollow relief from rag, wood, &c.

The rag or wood, &c., is reduced in hot water to a pulpy mass. Pulverised chalk, umber, or bone black may then be added. The mass is then formed in moulds to the shape required, and dried, when the articles are coated with any suitable varnish. Jan. 12, 1881. Price 2d.

164. J. Mellowes, Sheffield. Glazing roofs.

The roof consists of a series of rows of glass panes arranged in gradations, so that each row overhangs the row immediately below it. The panes at the upper ends enter a groove in the purlin. The lower ends rest on the top of the next purlin. The sides also rest in grooves in the bars of the framing. (*Pro. Pro.*) Jan. 12, 1881. Price 2d.

717. J. Woodward, Wolverhampton. Self-acting fastener for doors, windows, sashes, and frames.

This simplifies the action of spherical ball latches by making a cup, which is fixed to the bolt, and in which the ball seats itself. Feb. 19, 1881. Price 6d.

REGISTERED AND CERTIFICATED PLUMBERS.

REFERENCE has before been made by us to a new Plumbing Law which has been enacted in the United States, under which law no one will be allowed to work as a journeyman or master plumber unless he possesses a registration certificate, the possession of which will, it is thought, be some guarantee of competency. The *New York Sanitary Engineer* understands that the plan of plumbing to be adopted by the New York Board of Health will be presented to practical sanitary engineers, plumbers, and architects, at an early day, for their examination and advice. Meantime it publishes the regulations recently adopted at Washington, D.C., and Lawrence, Mass., as well as the forms for "registration" of plumbers adopted by the New York Board. The forms are as follow:—

Health Department,
New York, ... 188 .

Registration of Journeyman Plumber.

Under Chapter 450, Laws of 1881, and in compliance with the Rules and Regulations which have been established by the Board of Health, I, ——, a Journeyman Plumber, residing at No. —— street, do hereby register and make the following statement:—

That I am —— years of age, and served an apprenticeship of —— years with —— in the city of ——; that I have worked as a Journeyman —— years, and am now employed by —— doing business at —— street. And I hereby agree to comply with the Rules and Regulations that are and shall from time to time be established by the said Board of Health.

Signature.....

Health Department,
New York, ... 188 .

Registration of Master Plumber.

Under Chapter 450, Laws of 1881, and in compliance with the Rules and Regulations which have been established by the Board of Health, I, —— a Master Plumber, residing at No. —— street, and carrying on business at No. —— street, do hereby register and make the following statement:—

That I am —— years of age, and served an apprenticeship of —— years with —— in the city of ——; that I worked as a journeyman —— years, and have carried on the business as a Master Plumber —— years. And I agree to comply with the Rules and Regulations that are and shall from time to time be established by the said Board of Health.

Signature.....

The Brooklyn master plumbers contemplate calling a meeting to discuss the new law passed by the State Legislature conferring supervisory powers on the Board of Health in the matter of plumbing and drainage. Dr. Raymond, Sanitary Superintendent, says that every decent plumber would appreciate the new law. The only people who dislike it are builders of paste-board houses and plumbers who do cheap and unsatisfactory work.

The necessity of the adoption in this country of some such measures as have been taken in America was spoken of by Mr. Hellyer and by Professor Henry Robinson during the recent lectures on plumbing under the auspices of the National Health Society.

EASTBOURNE SANITARY EXHIBITION.

THE exhibition closed on Saturday, when there was a large attendance of visitors, who completely filled the large Pavilion as well as the annexe. In the afternoon Mr. E. Gregson Banner, C.E., lectured on "Sanitation and Ventilation." Dr. Ellis presided. The lecture was illustrated by models and diagrams. In the evening Mr. Isaac Shone lectured on "Defective and Effective Hydraulic and Pneumatic Drainage and Sewage Engineering." During the evening some experiments were made with Dick's patent fire *extincteur*. A large wooden structure, satnrated with tar and petroleum, was erected and ignited close to the annexe of the exhibition, and the rapidity with which it was extinguished by two small engines worked by Mr. Sinclair and Mr. Fuller was remarkable. After the closing of the exhibition an interesting presentation took place, a number of exhibitors having subscribed to present a combined testimonial to the secretary and treasurer. That presented to Mr. Schmidt, the treasurer, consisted of a silver tea-kettle, and that to Mr. Rodda, the secretary, of a mantelpiece clock, with pair of candelabra *en suite*. The presentation was made on behalf of the exhibitors by Mr. Councillor Hamilton, of Brighton.

The Awards.

The awards were announced during the day. The following are some of them:—

CERTIFICATES OF MERIT.—*In the Pavilion*:—Doulton & Co., Lambeth, fine art pottery, &c.; D. T. Bostel, Brighton, Bostel's patent tip-up lavatory basins, Hall's patented ventilator, and other sanitary appliances; J. A. Skinner, Eastbourne, valve-closets, &c.; F. G. Underhay, London, closets, pumps, well-frames, ball-valves, lavatories; Doulton & Co., Lambeth, water-waste preventers, baths and bath apparatus, sanitary appliances; W. H. Lascelles, London, red concrete window, paving and moulding slabs, and chimneypieces; Lincrusta Walton, new wall decoration, non-poisonous; The Silicate Paint Company, London, paints, enamels, &c.; Wilcock & Co., Leeds, glazed bricks, pottery, and sanitary apparatus; Doulton & Co., Lambeth, terra-cotta mantelpieces with patent fire apparatus; James Ed. Ellison, Leeds, conical perforated ventilating bricks and air-grates, valves, &c.; Papyrotile Company, London, the Papyrotile decoration; James Stiff & Sons, Lambeth, art stoneware, sewer air-traps, and terra-cotta, &c.; R. Boyle & Son, London and Glasgow, self-acting air-pump ventilators; Steven Bros. & Co., London, kitchen ranges and cooking apparatus; F. Fisher, Tunbridge Wells, electric bells, &c.; Chorlton & Dugdale, Manchester, mattresses and beds. *In the Annexe*:—George Jennings, Stangate, London, valve-closets and urinals; Charles Drake & Co. (Limited), Batterseas, concrete baths, floors, &c.; Spence's Metal Manufacturing Company, London, Spence's metal for jointing pipes, &c.; The Wilson Engineering Company, London, smoke-consuming stoves and ranges; Uriah Clark, Hellingly, Sussex, fancy and useful terra-cotta work, &c.; Frederick Edwards & Son, London, patent smoke-consuming slow-combustion grate; T. Constantine, London, smoke-consuming cooking range, and Dicks' patent fire-extinguisher; John Wright & Co., Birmingham and London, reflecting gas-cookers; Ritchie & Co., London, lighting and heating stoves; "Sunlight" Stove Co., Manchester, cooking stoves, baking and roasting apparatus; C. R. Stevens, Lewisham, patented steam and hot-air heaters; Sanitary Engineering and Ventilation Co., Westminster, scientific, sanitary, and domestic cisterns, &c.; A. Walker, Dulwich, concrete flooring, &c.; Jesse Pamphrey, Eastbourne, plaster models of houses; Bradford & Sons, Eastbourne, patent stoves and grates; William Sugg & Co., Westminster, lamps, burners, and ornamental globes, &c.; F. W. Reynolds, Blackfriars, London, portable steam-engines and mechanical tools; J. A. Skinner, Eastbourne, window-sashes, &c.; R. Adams, London, window-fasteners, sashes, &c.

HONOURABLE MENTION.—Thomas Bradford & Co., London, washing-machines; Robert R. Gibbs, Liverpool, boilers and furnaces; Gilmore & Clark, London, fire-alarms, ventilators, &c.; J. Jones & Sons, Bankside, London, boilers and coil cases; Manchester Water Meter Company, Ardwick, water-meters, &c.; E. Miray, London, sanitary appliances; S. Owen, London, baths and fittings; J. A. Skinner, Eastbourne, stoves, &c.; Webb's Worcester Tileries Co., Rainbow-hill, Worcester, for wood floor-blocks.

Mortuary for Kensington.—Mr. Reuben C. Green, solicitor, of Gray's Inn, applied at the Consistory Court on the 24th ult., on behalf of the churchwardens of St. Mary Abbotts, Kensington, for a faculty for the erection of a public mortuary upon part of the disused burial-ground adjoining the parish church. Mr. Churchwarden Bailey, Mr. R. Walker, architect, and Mr. R. Green, vestry clerk, were examined in support, and there being no opposition, the application was granted.

OBITUARY.

Mr. Chas. Lamb Kenney.—With much personal regret we record the death of this gentleman, which took place on the 26th ult. The son of the well-known dramatist James Kenney, and godson of one of even wider fame, Charles Lamb, himself accomplished, witty, and bright, Chas. Kenney took a position on the staff of the *Times* at nineteen as dramatic critic, and soon became recognised as a successful journalist and author. Later on he associated himself with M. Lesseps in the formation of the scheme for the Suez Canal, and then with Sir Joseph Paxton in some of his undertakings. He returned, however, to literature, and enjoyed a successful career, interrupted some years ago by an illness from which he never entirely recovered, and which in the end rendered continuous exertion almost impossible. His principal works are "The Gates of the East," the Biography of Balfe, the "Life and Letters of Balzac," and numberless operas and songs. He wrote the *libretti* of the "Grand Duchess," "Princess of Trebizonde," "La Belle Hélène," "Duck with 3 Beaks," and an English version of standard Italian operas published by a leading firm of music-sellers. In his early days his facility in the production of impromptu verse and epigrams was remarkable, and, indeed, continued to be so to the last in the intervals of ease which his malady afforded. He has left a widow, who had tended him with great devotion, and two children, one of whom, Miss Rosa Kenney, has given such promising evidence of ability as an actress that it is a matter for surprise that some leading London manager has not afforded her a fitting opportunity to display it further. The lamented death of her father, bringing to mind the good work he did in his time for actors and managers, as critic and dramatist, may lead to this desired result. We have not so many young ladies now on the stage capable of the supreme efforts required in the Shakspearian drama, that we can afford to neglect so promising an aspirant as Miss Kenney. The funeral took place at the Brompton Cemetery on Tuesday morning last. Besides the chief mourner, his son, Mr. Charles Horace Kenney, and various members of his family, a large number of friends had gathered to pay a last tribute of respect and affection, including Mr. George Rose, Mr. Sutherland-Edwards, Mr. Dion Boucicault, Mr. George Boucicault, Mrs. Alfred Mellon, Dr. Rice, Mr. Davison, Mr. Bosey, Mr. Aylmer-Gowing, Mr. S. Godwin, Mr. H. A. Nattali, Mr. Commissioner Hazlitt, Mr. George Coleman, and Mr. Charles Boyd. Mr. Kenney's resting-place is near to that of his late father, Mr. James Kenney, and his sister, the Baroness Mergey.

Mr. James Sandby Padley, County Surveyor for the division of Lindsey, Lincolnshire, died on the 18th ult., at Skegness. He was in his ninetieth year. He was a pupil of Captain Stevens, of the Royal Engineers, and assisted in the Ordnance Survey of Lincolnshire and the counties adjoining. In 1820 he was appointed county surveyor for the parts of Lindsey, a position which he held to the day of his death. During this period of fifty-eight years he constructed more than fifty bridges in various parts of the division. In 1826 he was appointed general surveyor to the Commissioners of Sewers acting at Lincoln, and continued to hold that office to the time of his death. In this capacity he carried out extensive improvements to the river Witham, and to the Langworth river, and he also designed and carried out the important work of the Torksey drainage, by means whereof the flood waters are pumped into the river Trent. He was surveyor to the Lincoln Turnpike Trustees for sixteen years. In 1875 he projected, in concert with Mr. Teague, engineer to the Lincoln Waterworks, the water supply to the town of Market Rasen. In 1842 he completed the survey, and published a map, of the city of Lincoln, which he revised in 1851, and again in 1868. In 1851 he published a work on the ancient monastic, ecclesiastical, and domestic edifices of Lincolnshire, illustrated with engravings, plans, and elevations of the buildings described.

Messrs. W. H. & L. Collingridge, of the *City Press*, announce the completion and occupation of their new buildings, 148 and 149, Aldersgate-street, which have been erected upon the site of the offices destroyed by fire in April of last year.

THE FULHAM SMALL-POX HOSPITAL.

FURTHER steps were taken last week, before a Divisional Court of the High Court of Justice, sitting in the Rolls Court, in the action that is now pending between Chambers and others against the Metropolitan Asylums Board for damages in the establishment, maintenance, and management of the Fulham Small-pox Hospital, and for its discontinuance. Already had the plaintiffs made application to the Court for an injunction to restrain the defendants from using the hospital for the reception of small-pox patients till the hearing of the case, but Mr. Justice Bowen, before whom the case came, adjourned the motion for injunction till the action came on for trial, and it was against this order that the plaintiffs now appealed.

After hearing the respective counsel, the Court suggested that the defendants might very well undertake not to send into the hospital any other patients than those coming from Fulham or from the adjacent parish, Hammersmith, till the hearing. In this arrangement Mr. Bompas (for plaintiffs) was willing to concur, but as Sir Hardinge Giffard, on the other side, was unable to enter into it without consulting the Local Government Board, time was given for this purpose; but as no action has since been taken, matters will remain as they are till the 5th of September, when a Divisional Court will sit to hear the case.

We need scarcely say that considerable interest, both local and external, is excited. It is time that the power of ruining a neighbourhood exercised by the Metropolitan Asylums Board should be curtailed.

The serious damage that has been occasioned to the owners of land and of house property, as well as to business interests generally in the vicinity of this hospital, is incalculable, and suggests that the effort to remove this plague-spot should receive more aid than strict *law* can give.

ARCHÆOLOGICAL SOCIETIES.

Yorkshire.—The members of the Yorkshire Archæological and Topographical Association went on an excursion to Helmsley and Rievaulx Abbey on Monday last, when the ruins of Helmsley Castle were described in a paper by Mr. G. T. Clark, Mr. J. T. Micklethwaite, F.S.A., discoursing upon the ruins at Rievaulx. Those who took part in the proceedings had put into their hands a well-written illustrated programme of the proceedings, which detailed the main historical facts in connexion with the places visited.

Somerset.—The annual meeting of the Somerset Archæological Society was held last week at Clevedon, under the presidency of Mr. Edmund H. Elton, who delivered an address. It is twenty-one years since the Society held its meeting in this part of the county. The report of the council showed the position of the Society to be satisfactory, and recommended the formation of a *Bibliotheca Somersetensis*,—a work which it was considered that the county should be no longer without. The vice-presidents were re-elected, with the addition of Dr. E. A. Freeman. The members subsequently visited Clevedon Court, at the invitation of Sir Arthur Elton, who read an interesting paper descriptive of the building. Proceeding to Yatton, they inspected the fine old prebendal church, dedicated to Saint Mary the Virgin. The church was described by Mr. B. Edmund Ferrey, Dr. Hardman, and Mr. E. Green. Subsequently a visit was paid to the Old Rectory, at Yatton. In the evening a meeting was held at the Public Hall for the reading and discussion of papers on subjects of local interest. Mr. C. E. Davis, F.S.A., gave a description of the recent Roman discoveries in Bath. He explained that the hot-water springs of Bath were utilised by the Romans for bathing to a considerable extent, but until the year 1750 all that was known of the hot springs was merely the sort of reservoir into which the water came from the bowels of the earth, and until that time that was the only part of the baths used for bathing. In 1755 some excavations were made near the abbey, and the result was the discovery of a large system of baths, and in consequence of the excavations which he had recently made at the expense of the Corporation he had been enabled to make a correct plan of them. In 1871 he found a large Roman drain, and by clearing out this they were enabled to carry the excavations to a greater depth, and the result was that they discovered recently a large bath 80 ft. long and 40 ft. wide within a large hall exceeding 120 ft. in length. Subscriptions were started with the object of clearing the baths, which were built of the most massive masonry, and making them available for the public. The excavations had revealed the fact that these baths occupied about one-fourth of the ancient city of Bath.——Mr. Jerom Murch said not only the citizens of Bath, but the archæologists of Somersetshire, were much indebted to Mr. Davis for the interesting discoveries he had made. They had not been made by Mr. Davis in consequence of any precise commission given him by the Corporation, but they were made by him month after month as the result of untiring energy and hard work, pursued oftentimes in the face of much discouragement. Some idea of the extent of these baths would be formed when it was stated that they were four times the size of the abbey. When this great work was completed, and the whole area was thrown open, as he hoped it would be, they of the present generation would be able to form a fair idea of the magnificent baths which the Romans constructed in the city of Rome itself. Prebendary Scarth considered this one of the most remarkable discoveries yet made. On the second day there was an excursion to Tickenham, Wraxall, and Ashton Court. On the return journey, Long Ashton Church, Flax Bourton Church, and Backwell Church were visited, Mr. Ferrey describing the architectural features of each.

THE VERGERS OF YORK MINSTER.

THE Very Rev. the Dean has allowed his choler to obscure his logical faculty. He says he has from time to time received anonymous imputations concerning the vergers. What is this but acknowledging that hosts of others have been stirred, like myself, to indignation and complaint? But he dismisses them with the stereotyped and conventional formula of mechanical thought: "I have treated them with the contempt such communications deserve." Had he said "This is the first time I have heard any remark about the vergers," there would have been some excuse for the warmth of the epithets he applies to me and the other complainants; but, as it is, there cannot be, to any reasoning mind, a stronger illustration of the French adage, "*qui s'excuse s'accuse.*" He then says that the visitors to York Minster are of "various degrees of intelligence, and it must be very difficult to give information which shall be equally acceptable"; *ergo*, the vergers are to persevere in doling out that of a very low, and in the cases quoted by me, offensive standard. The Dean adds that I do not "give any clue to my mental capacity." Perhaps this will satisfy him. I desire to visit a cathedral under this condition. I do not object to make a liberal contribution, but I desire to be left alone to make my own inspection, my own observations, my own reflections, without the obtrusion of an illiterate and would-be facetious verger. This privilege has been accorded for some time at Peterborough and Winchester, without any damage to anything but the "tips" to the vergers. If this desire is an evidence of a poor and mean intellectual capacity, it is shared by thousands who have visited those cathedrals and gratefully acknowledged the concession.

I do not wish to offend the feelings of the friends of the Dean, or to gauge their mental capacity, but I cannot help thinking they must be blessed with the possession of an immense amount of politeness; for I do not understand how they could return to the deanery and acknowledge the "interesting information" imparted to them, if it was of such a character as that vouchsafed to me and twenty others by the Dean's pet verger.

The Dean then speaks of "the complex and difficult duties" of the vergers. I thought their functions were to open the doors of the stalls of the Dean and Canons, and to show the congregation to their seats. Is this part of their duty complex or difficult? Or is it both? Does the performance of it entail such a mental strain that when they address themselves to the other portion, that of receiving the sixpences and showing the visitors over the edifice, they are obliged to seek relaxation in being vulgar and trying to be funny? But the Dean says this is "frivolous and cowardly," so I very humbly apologise to him. If I can find courage I will make an *auto-da-fé* of my Britton, my Willis, and even the little guide-book to the minster. I will invoke Murray, not, as he is about to do, to publish a fresh edition of his Yorkshire, or, at least, to omit that part pertaining to the cathedral; and should I again visit that sacred edifice, I will endeavour to listen with the most profound attention to the "complex and difficult" verger. I cannot expect, after the infamous conduct of which I have been guilty, to be invited to the deanery, but I will make every effort, like the Dean's friends, to express "an approval of the information imparted," specimens of which will be found in the *Builder* of August 13th.

F. S. A.

ST. MARGARET'S WESTMINSTER.

SIR,—Every true artist and lover of the really picturesque and beautiful will agree with you that it would be an act of the greatest Vandalism to destroy St. Margaret's Church. It only hides a small portion of the Abbey as seen from one side, and then not only serves to show off and assist the grand proportions of the latter, but unites with it to make a grouping of extreme beauty. Indeed, the Abbey would lose much of its venerable and historic appearance by the demolition of any of its Mediæval surroundings.

Unfortunately, only too many of the finest churches in Europe have lost a great part of their interest by the pulling down of all the contemporary buildings about them. Milan Cathedral, for instance, is now utterly dwarfed and disfigured by the erection of a gigantic quadrangle of "Renascence" houses all round, thus giving it the appearance of an imitation Gothic church in a London square.

Looking towards Westminster Abbey from Victoria-street, the harmonious group of Gothic buildings forms one of the most striking and splendid *coups d'œil* in the world, and one which would be greatly deteriorated by the abstraction of St. Margaret's; while, looking from Parliament-street, the large trees on the north side of St. Margaret's conceal nearly the whole of what itself covers of the Abbey, so that it would be necessary to cut these down also before the object desired by the advocates of the demolition could be attained.

What really does conceal the Abbey without providing any compensation in the form of its own beauty, is the hideous block of buildings flanking Abingdon-street, and if money is to be spent in improving the precincts of Westminster Abbey, it should not be by destroying the pretty little church with so many historic associations, but by pulling down such obtrusive and vulgar edifices as these and the Aquarium.

EVACUSTES.

THE WORD "NATURE" IN ART-DISCUSSIONS.

SIR,—The misuse of the word "nature" has vitiated most of the art-discussion for the last five-and-twenty years past. The word "nature" has so many connotations that when it is used in reference to art questions it is not noticed that it is being used at one time as implying one thing and at another something entirely different. Sometimes "nature" includes all that is possible to be, the universe; at others, "nature" means only that part of nature which is not man, and which is unsophisticated by man; and in yet another sense "nature" means only that which is right in human and other nature.

Now, art-discussion would be more fruitful of practical advantage if we would but determine to use the word "nature" in that first signification, namely, as including all that is possible to be, and then writers would not have to apologise for thinking, as Mr. Colling does in his letter to the *Builder* of the 28th ult., that the "mathematics and geometry are closely allied to laws which exist in nature." Why, of course they are,—they are a part of nature; they are an exposition of the relations of quantity and configuration in nature; they are not evolved out of man's inner consciousness, but are founded on his experiences of being. But nature includes both symmetry and irregularity, well-being and ill-being, right and wrong. It is not, then, a sufficient reason that anything should be adopted in art because it exists in nature; we have to show why one form of nature should be adopted in preference to another,—that such and such a treatment is better for our human well-being, our taste, than another. It is on this ground that the argument for the regular or the irregular should be fought out. I could, of course, enter into the argument concerning the geometrical on this

ground, but it is of no use discussing any art-topic till there is a complete understanding about the use of the word "nature." It should, however, be recollected that geometry does not deal with the regular alone. Regularity and irregularity are two extremes, between which nature, art included, is always striving to steer a middle course. W. Cave Thomas.

CONDITION OF FAREHAM.

Sir,—Permit me a little of your valuable space to vindicate my report of the deplorable sanitary arrangements of Fareham, portions of which you remarked upon in your edition of the 20th inst.

No denial of my charges has been given in the letter of the Fareham Local Board to you. It is a "hornets' nest" I have stirred up,—a very unfragrant one,—and if the Fareham Local Board wished to keep secret and continue their present sanitary system they could not have done worse than to write to you the letter of August 27; for, firstly, my *exposé* of the dangerous contamination of the water supply through the closets being directly connected therewith without the intervention of an intermediate tank, is admitted. Intermittent water supply is also admitted, though if there were constant supply it would be but a very weak defence against the ingress of sewage gas, and, as I will presently show, of something worse. The Board admit the water is turned off from ten p.m. to six a.m., and it is also turned off Sundays from six p.m. to eight p.m., and in the hot seasons at other hours, and, of course, at all seasons occasionally for special purposes. The purity of the water when it starts from the works is mentioned in my first letter, and it is the more grievous that so rare a blessing should be wilfully spoiled by its guardians; and the repetition of my testimony by the Fareham Local Board, as an answer to my charge, is remarkable. Now, to further illustrate the dreadful evil. A closet on the said objectionable principle, attached to a large house in the West-street, not long since became choked, and the "exhaust" was even allowed to fill the pan and actually ran into the water-pipe, and, percolating through the service, the horrid mixture was actually drawn from the taps in the house, and, consequently, must have been supplied to adjoining houses. Imagine the result had cholera or other deadly epidemic been in the house! I suppose no high sanitary authority is needed to tell us that it would have been at once spread over the entire area contaminated by the said closet, and even the whole water service of the town itself might have been thus impregnated with the germs of fatal disease. It may be said this is an extreme case; but on inquiry I find that in cottage closets and with untidy tenants it must often occur. Comment is needless, save, perhaps, recording publicly that nothing but insulating all closets from the water supply, by intermediate tanks or cisterns, will protect the town from some frightful epidemic, always now threatening it.

You are told regarding my second charge, that "the effluent water, after filtration and deodorisation, pass into salt-water mules away from Portsmouth." Now mules away from Portsmouth brings it (the sewage of 6,000 people) where I described it, viz., on the shore of Fareham quays and town. I assert that nothing worthy of the name of filtration or deodorisation is effected. Why do not the Fareham Local Board state the deodorising means and material used; and what *they* understand by "filtered"? The fact is, that there is practically no filtration or deodorisation whatever, as flint stones are the only material used. There are small tanks at the outfalls into which the sewage passes at one end, and out at the other direct into the Channel when the tide recedes. The solid matter which deposits itself *voluntarily* at the bottom of the tanks is removed at the convenience of the contractor, and at irregular intervals of about six months. But all that is offensive and poisonous in the sewage still is vomited forth after every tide, close under the shore which bounds the lower part of the town, and wends its way down the Channel into the harbour, most of it to varnish her Majesty's numerous shipping, and swelter in the summer sun (when we have any), and the rest, opposed by the returning tide, heads back up the Channel, and, wearied by its first voyage, sticks permanently to the Fareham mudbanks, and twenty years of tidal sewage deposits have left the acres verging the Channel leading from Fareham to Portsmouth Harbour the stinking pestiferous region it is.

And the sewers. I state positively that cellars are flooded from the sewers in the chief street, notably those of a leading hotel, of a large bakery, and of the former residence of two leading townsmen, referred to in my letter to a local paper. The current denial given is inexplicable in the face of facts; and I know that, in connecting the drain of a block of houses lately, the main sewer was found full of gravel and mud, and stagnant water. To make even a nominal connexion a bend was used, entering the sewer vertically. Perhaps some allusion, in boasting of the "filtration system," was meant to the "flushing tanks" at two or three points in the town. Perhaps not, for they are simply pits capable of being filled with water and then let out suddenly into sewers. Contents are not otherwise removed, and the Fareham Local Board tells us how incapable the sewers are of dealing with a sudden rush of liquid. *Apropos des bottes*, let me relate that once some nasty person deposited a lot of night-soil at a frequented corner of the town. The nuisance at once appealed to the sanitary reverberations of the Fareham Local Board, who immediately dashed a lot of fresh lime on the fetid mass. Result? "Foul, sour gases from the release of gases in the fatty deposit." Sanitary science has not here reached the stage as the modern "Noah" in the study of the wonderful deodorising powers of simple soil.

A few words only on the rest of the Fareham Local Board's protest. As to the churchyard, after burying 100 bodies per annum for seven years since it was reported virtually full, the echoes have, towards providing a cemetery, only now reached the stage of "being in correspondence." I fear pen and ink will not buy ground or build cemetery buildings and 12 ft. high retaining walls, &c., &c. It takes a lot of money now to satisfy the ever-increasing requirements of the authorities. Nor is any comfort to be had, even remotely, that the sanitary rate is high, when it is known it would be much higher and worse, but have been long spent, seeing the results described. A word more in letter in your columns to tell us that we are to have rates and sewer rate in peace? And why in the last seven Local Board not add new rent-free lands there, too, so have meagre returns for our money. Also "Fareham is in directories." Nothing like facts. As to how Fareham is "reputed," the public will now read for themselves and wonder. Happily, no epidemic. No; but how soon will the vile state of affairs permit our escape? Two or three closets such as described, an unhealthy season, a match applied, in the shape of imported epidemic, to the magazine of evils quite ready to explode, then *exeunt omnes*. Personally, I and others fervently hope the "happily" will last a little longer, till we can get clear of the unnaturally poisoned atmosphere and water supply, and the piled up corpse ground of this *naturally* nice town.

I am ready to subscribe a guinea to a fund to pay an expert, nominated by you, to report as to the truth or falsehood of my strictures. Quæstor.

Books.

Practical Ventilation and Warming, with Illustrations and Examples. By Joseph Constantine, Manchester. London: J. & A. Churchill, 1881.

The special feature of Mr. Constantine's book is that it describes and illustrates the mode of heating and ventilation actually adopted in various public buildings, such as the Pentonville Prison, Free Trade Hall, Manchester, Manchester Royal Exchange, a concert-hall, and so on. It gives suggestions, too, on the construction and heating of disinfecting rooms and Turkish baths, and we have no hesitation in pointing it out as a useful contribution to the existing means of obtaining knowledge in respect of subjects the importance of which is more recognised every day.

Handbook for the Cathedral Church of St. Fin Barre, Cork. By Richard Caulfield, LL.D. Cork: Purcell & Co. 1881.

Dr. Caulfield was the honorary secretary to the committee for rebuilding the Cathedral of St. Fin Barre, and has prefaced his excellent little guide with a pithy, yet comprehensive, sketch of the early history of the site and the proceedings which led to the erection of the present building from the designs and under the loving care of the late William Burges, architect. Our early volumes contain illustrations and particulars of this cathedral, which must be regarded as its architect's chief monument. His design, it will be remembered, was selected in competition, and about 100,000*l.* have been spent upon it, leaving many of the intended decorations and some of the furniture yet unsupplied; the designs, however, were all made, and are in the hands of the authorities. So much of the carving and other work is symbolical, and so many of the windows and fittings are erected as memorials of individuals, that half the pleasure derivable from a visit to it would be lost without a proper guide-book, and this, Dr. Caulfield, in fulfilment of a promise made to the late Bishop and to Mr. Burges, has admirably supplied. It includes a plan and other illustrations, and describes pithily every portion of the building. The stained-glass windows, of which there are many, were all executed by Messrs. Saunders & Co., the cartoons throughout being made by Mr. H. W. Lonsdale, with the exception of those for the three choir clearstory windows supplied by Mr. F. Weekes.

VARIORUM.

The third edition of "The House Owner's Estimator: or, What will it Cost to Build, Alter, or Repair" (Crosby Lockwood & Co.) is edited by Mr. Fredk. T. W. Miller, A.R.I.B.A., and contains additional prices and information. It is not unusual to hear a house-owner say, "I wonder what it would cost to put in a bow-window," or "What would be the expense of another story." The object of this little book is to afford, broadly, an answer to such questions, and it contains much other information useful to owners and occupiers.——We ought to have mentioned before now that a third edition has been published of "Metropolitan Rating," by Edward Ryde and Arthur Lyon Ryde. It consists of a summary of appeals heard before the Court of General Assessment Sessions, with a synopsis of the "Valuation (Metropolis) Act, 1869," and is an absolutely necessary book for surveyors and valuers.——The new number of the *Nineteenth Century* gives evidence of the open eye which Mr. Jas. Knowles keeps on the progress of events, and the success with which he makes his Review present a discussion of current questions. Thus, to mention but a few of the heads, the Deadlock in the House of Commons is commented on by Mr. F. Harrison, Bread Reform by Miss Bevington, *Scrutin de Listo* by M. Reinach, the Workman's View of Fair Trade by Mr. Geo. Potter, and France and North Africa by the Earl de la Warr. None will read it carefully without gain.

Miscellanea.

St. James's Church, Paddington.—In the Consistory Court, before Dr. Tristram, Chancellor of London, application has been made by the vicar (the Rev. W. Abbott) and churchwardens of St. James's district parish church, Westbourne-terrace, for a faculty to reconstruct the body of the church, at an expense of 15,000*l.*, according to plans prepared by Mr. Street, R.A. Objection was taken to the granting of the faculty on the ground, firstly, that the proposed outlay was extravagant, and secondly, that by the proposed reconstruction there would be a decrease in the number of the sittings. The Chancellor, in giving judgment, said that Mr. Street had proposed to add to the width of the church, and to erect galleries, which would increase the sittings to nearly the original number. But the additions were not on the plan as filed and submitted to the Bishop of London, and, therefore, in his opinion, there should be a supplemental petition and an amended citation issued before he could grant the faculty. He knew there could be an appeal, but he hoped that those who opposed the granting of the faculty would consider what he had said. If there was no further opposition, the work could proceed during the present vacation, and be finished by the end of the vacation next year. The learned Chancellor said he should see the Bishop of London on the point he had stated, and if, in a week after the citation was published, there was no further objection, the faculty would be issued, and the works could be commenced. Order accordingly.

Termination of the Strike in the Wrought-iron Nail Trade.—An adjourned conference of wrought-iron nail manufacturers of the Birmingham, Dudley, Halesowen, Sedgley, and Old Hill districts was held at Birmingham, to consider the demands of the men on strike for the restoration of the 1879 list. The operatives originally struck for an advance of 30 per cent., but they modified their demands to the 1879 list, which is about 25 per cent. below the list of 1875. During the past twelvemonths, however, the nailers have been paid about 25 per cent. less than the 1879 list, and they accordingly went out on strike about two months ago to the number of nearly 30,000. About 2,000 have returned to work at the advance, but the remainder were still out pending the decision of the meeting. After a lengthy discussion, it was resolved, on the motion of Mr. Perry, seconded by Mr. Russell, "That the demands of the workmen be conceded, and the 1879 list be paid in future." The decision was communicated to Mr. John Price, the leader of the operatives.

The City Church and Churchyard Protection Society.—A special meeting of the Council of the City Church and Churchyard Protection Society, presided over by Mr. J. Clarke Mould, was held to receive the report of Mr. Henry Wright, honorary secretary, on the proposed destruction of St. Matthew's, Friday-street, a church with a good congregation at both Sunday services, the rector of which is the succentor and a minor canon of St. Paul's Cathedral, Dr. Sparrow Simpson. The following resolution, proposed by Mr. G. H. Birch, A.R.I.B.A., and seconded by Mr. Bowes A. Paice, A.R.I.B.A., was unanimously carried:—

"That the Council of the City Church and Churchyard Protection Society, whilst admitting there may be no special beauty in the church of St. Matthew, Friday-street, yet consider that every opposition should be offered to its proposed destruction, both from principle and on account of many of the provisions in the scheme for the Union of Benefices."

An Unfounded Imputation.—Mr. G. F. Lyster, the respected engineer to the Mersey Docks and Harbour Board, on Saturday last, in the Liverpool City Police Court, appeared in support of a summons for libel taken out by him against the printer and publisher of a weekly publication called the *Wasp*. It seems that in the number for July 30, the following words were printed, under the head of "Answers to Correspondents":—"Jerry.—We do not know what commission the Dock Board Engineer gets from the cement-makers." It was admitted by the defendant that he had no ground whatever for the grave imputation which these words conveyed, and that they were, in fact, merely a "joke,"(!) no correspondent having asked for information on the subject. Mr. Lyster formally testified as to the absence of any foundation for the statement made. Subsequently, an apology was tendered and accepted, and Mr. Lyster withdrew the summons.

Land Reclamation in Ireland.—The Commissioners of Public Works, Ireland, have just issued their consolidated award for the repayment of the loan obtained from Government for the Upper Inny drainage works. More than 11,000 acres are included in the award as having been saved from the injurious effects of flood waters, but the quantity of land actually benefited far exceeds 11,000 acres, because the lands surrounding the 11,000 acres are now relieved from the injury they formerly sustained by their proximity to the 11,000 acres of flooded land now drained. The works, which now extend along eighty miles of rivers and tributaries, passing through four counties, are the largest yet completed under the General Drainage Act of 1863, including the erection of many public road bridges of large span, the erection of weirs and sluices, together with two large self-acting regulating weirs, the first of the kind tried, and presenting many novel features for the control of the flood-waters. The works were designed and carried out under the direction of the chief engineer, Mr. James Dillon, M. Inst. C.E., of London and Dublin.

Improvements at Hastings.—Mr. Charles H. Cooke, the architect to the Royal National Lifeboat Institution, visited Hastings a few days ago, and conferred with Mr. William Andrews, the borough surveyor, with respect to the extension of the sea-wall, opposite the site of the proposed new lifeboat house in the Fish-market, which is to occupy the site of the old Custom-house lately washed away owing to the defective character of the foundations. It has been decided to extend the sea-wall 52 ft. to the eastward in its present line, and as soon as this has been completed, the erection of the lifeboat house will be proceeded with, from the designs of Mr. Cooke. Workmen are now engaged in underpinning the wall to the eastward of the groyne near the site, and when this is accomplished the wall will be extended.

"A Nice Mess."—According to returns furnished by the engineer of the Metropolitan Board of Works, the average daily quantity of sewage pumped into the river Thames is 318,169 cubic mètres at Crossness, and 426,686 cubic mètres at Barking, equivalent to about as many tons by weight.

"Bold-street, Liverpool."—Referring to the notice, under this heading in our last issue, of Messrs. Van Gruisen's premises, Messrs. Clark, Bunnett, & Co., write to say that the wrought-iron grilles and gates were manufactured, supplied, and fixed by them, as well as the hand-power lift.

Artisans' and Labourers' Dwellings.—The site of Peartree-court, situate between Clerkenwell-close and Farringdon-road, has been purchased by the Peabody trustees for the purpose of erecting dwellings under the Artisans' and Labourers' Dwellings Act.

Melbourne International Exhibition, 1880-81.—A desire has been expressed to present a supplemental testimonial to Sir Herbert Sandford, and a committee is being formed to make the necessary arrangements.

The Architectural Association has just had its twelfth annual excursion, Worcester and its neighbourhood having been the locality chosen. The excursion was carried out in accordance with the programme.

TENDERS

For new premises and alterations to Hall, Harp-lane, Great Tower-street, for the Worshipful Company of Bakers. Messrs. Clarke & Shoppee, architects. Messrs. S. Young & C. H. Shoppee, surveyors. Quantities supplied:—

Macey & Sons	£11,835 0 0
Stimpson & Co.	11,833 0 0
Patman & Fotheringham	11,650 0 0
Higgs & Hill	11,477 0 0
Scrivener & Co.	11,438 0 0
Clark & Bracey	11,239 0 0
Langmead & Way	11,190 0 0
L. H. & R. Roberts	11,137 0 0
Geo. Smith & Co.	11,072 0 0
M. Manley	10,942 0 0
Stephens & Bastow, Bristol	10,889 0 0
W. Brass	10,603 0 0
E. Lawrance	10,485 0 0

For rebuilding Nos. 19, 20, and 21, Old Bond-street. Mr. T. T. Wimperis, architect. Quantities by Mr. Hilton:—

Simpson	£16,451 0 0
Clark & Manoocb	15,590 0 0
Aldin & Son	15,390 0 0
Thorn	15,320 0 0
Brass	14,702 0 0
Fish	14,700 0 0
Bywaters	14,431 0 0
Patrick & Son	14,425 0 0
Scrivener & Co.	14,397 0 0
Macey	14,396 0 0
Langmead & Way	14,200 0 0
McLachlan & Sons	13,984 0 0

For road and sewer works on the Leytonstone-road Estate, for the United Land Company (Limited):—

W. Porter	£2,684 11 7
A. Walker	2,649 0 0
Nowell & Robson	2,500 0 0

G. Impey	2,010 0 0
J. Bloomfield	2,009 0 0
A. Nicholls	2,000 0 0
J. G. Truman	1,999 0 0
Ford & Everett	1,974 0 0
Beadle Bros.	1,731 0 0
Jesse Jackson (accepted)	1,725 0 0

For the erection of houses at Langley Park, Sutton, for Mr. J. L. Plumbridge. Mr. Alex. R. Stenning, architect. Quantities supplied:—

	One House.	Five Houses.	Picked Stocks.
R. P. Barnes, Chiswick	£1,940	£9,400	£9,300
J. Jesl, Epsom	1,786	8,9.0	8,950
Young, Cochrane, & Co. Kennington	1,750	8,700	8,470
Watson & Dennott, Dulwich	1,658	7,900	7,750
Bottom Bros., Battersea	1,486	7,400	7,550
Vernon & Ewens, Watmnstr.	1,500	7,118	7,000
M. N. Rowles, Acton	1,382	6,862	6,862
W. Crockett, St. Pancras	1,400	6,825	6,625
W. Hobern & Co. New Kent-road	1,200	5,995	5,950
A. Porter, Waltham	1,187	5,9'0	5,800
J. D. Brutton & Son	1,214	5,570	5,545
Howe & White, Wallington	1,095	5,15)	5,400
G. Avis & Co. Peckham	1,005	5,375	5,325
B. J. Humphris, Sutton	1,110	4,880	4,810
Smith & Bullied, Croydon (too late)	1,666	8,330	—
J. Warr, Croydon (too late)	1,364	6,779	6,769

For the erection of a house at Bromley, Kent, for Mr. A. E. Willett. Quantities by Mr. W. B. Brown. Mr. Alex. R. Stenning, architect:—

S. J. Jerrard, Lewisham	£3,343 0 0
J. C. Arnaud, Bromley	3,552 0 0
Syme & Duncan, Beckenham	3,500 0 0
S. Sabey & Son, London	3,393 0 0
S. Crossley, Bromley	3,389 0 0

For the erection of a house at Bromley, Kent, for Mr. C. Nickalls. Quantities by Mr. W. B. Brown. Mr. Alex. R. Stenning, architect:—

S. J. Jerrard, Lewisham	£3,143 0 0
J. C. Arnaud, Bromley	3,987 0 0
Syme & Duncan, Beckenham	3,850 0 0
T. Crossley, Bromley	3,688 0 0
S. Sabey & Son, London	3,664 0 0

For building a new lodging-house in rear of 90, Camberwell-road, for Mr. Lee. Mr. St. Pierre Harris, architect:—

	Lodging-house.	Covered Way.
Taylor & Son	£3,889	£10 0 0
Hainsman	3,867	22 19 6
G. & S. Fisher	3,375	16 0 0
Grover	3,348	17 0 0
Eldridge & Gee	3,093	17 0 0
Taylor & Parfitt (accepted)	2,993	18 0 0

For repairs and painting at the Wapping Charity Schools, for the Trustees. Mr. F. J. Westley, architect:—

Taylor & Parfitt, accepted.

For the restoration of the parish church, St. Deverux, near Hereford. Mr. Wm. Chciake, architect:—

	Design A.	Design B.
Pearson & Son, Ross	£1,250	£1,051
King, Gloucester	1,187	937
W. Cullis, Hereford	1,100	800
W. Birrell, Shrewsbury	1,072	872
Huckson & Warwick, Hereford	847	700

For erection of farmhouse, &c., at Farnborough, for Sir J. Lubbock, bart., M.P. Messrs. Baxter, Payne, & Lepper, architects:—

The "Jubilee" of the British Association.

IT is difficult to estimate rightly the characteristics of our own time, or of a time close to our own, and there is among most men a tendency to unduly depreciate the present, to look back to greater things which were done in former times, and to regard the achievements of their own day as comparatively slight and wanting in the elements of grandeur which characterised the men and the achievements of some great epoch of the past. Those who are interested in artistic and architectural subjects especially are very familiar with this idea. Great and original architecture seems a thing of the past; painting is a much more feeble power in modern life than it was in the Cinquecento period; sculpture is far below what it was with the Greeks; no second Shakspeare has renewed the glory of the Elizabethan drama. The view taken by the *laudator temporis acti* cannot but be admitted to be, in the main, reasonable and true, if sometimes pushed too far, in regard to this class of the subjects of human study and interest. But those who therefore think that we have fallen on a weak and uninteresting period of human history forget that an age weak in one direction may be strong in another direction, and that it is often exactly when one class of faculties is comparatively weak and imitative, that another is strong and active in origination.

The reflection could not receive more marked illustration than by the comparison which the fiftieth anniversary of the British Association naturally suggests between the position of science now and when they held their first meeting in the same city. The result is really almost startling. It needs but to give this glance backwards in thought, to the state of the scientific world fifty years ago, to realise that we are living in one of the most remarkable epochs in the history of mankind. The mere material progress represented by the railway and electric telegraph system would be a great deal; they are certainly the most marked and important steps in what may be called the social mechanism of life that we know of in history, and their moral effects have indirectly been very great also. But these inventions and their results sink almost into insignificance when we look at the step which has been made in regard to our general theory of the history of our planet and the history of life on it, of our relation to our physical antecedents and our physical surroundings, of the very idea of what life means, which the deductions of science have led to during these fifty years. The step is really a tremendous one, and even to say that the epoch is as remarkable as that in which Galileo and Newton discovered some of the main truths about the solar system is far short of the truth. The discovery of the powers of spectrum analysis, and the consequent capability to grasp at the physical constituents even of the fixed stars, may be sufficient to set against that of the laws of gravitation by Newton; but some of the leading subjects of investigation of modern science are of a much more delicate and complicated nature than any investigations which are concerned with bodies moving by mathematical laws. The study of the infinite varieties of life on this planet, of the infinite varieties of disease too, and the manner in which they are produced and may be checked or nullified, is a study more complicated and requiring closer and more multifarious experiment and investigation than the apparently grander and more sublime, as well as more ancient, science of astronomy. But the influence of the study of life, past and present, on this earth, on what may in one sense be called our moral conception of life and its problems and duties, has been a tremendous one, where its significance has been grasped at all; and there has been no other epoch in which the influence of science upon man, not merely in regard to facts, but to the inferences from those facts, has been so immense and so important as it has been during great part of the last fifty years, and more especially during the last fifteen or twenty. To those who think at all about the meaning of what they hear, the facts of the palæontologist and of the physiologist, wonderful and interesting as they are, are merely the skeleton on which will grow, is growing even now, a whole living body of new social and moral beliefs.

It is out of our province to pursue this view of the subject; utterly impossible, at the same time, to refer to recent scientific progress without a side glance at its inevitable logical results. Avoiding that ground, however, and keeping to the purely scientific view of the subject, we cannot but be struck, quite apart from the practical interest of many scientific discoveries considered in detail, with the general effect of increased scale of everything, increased range of mental vision, which has been opened to us during the last fifty years. Through the "perspective glass" now presented to us by science we look back and around us, and are astonished at the way we have come and the distances that open out on all sides, and the unexpected relations we discern between phenomena once supposed to be isolated and disconnected. Time has stretched out behind us to immeasurable and almost unthinkable periods; epochs once regarded as distant are now but as yesterday; events which happen to-day, forms of life that are familiar to us, are shown to have their real originating causes in a past more remote than our fathers of the last generation ever imagined as existing at all; facts apparently, to the unscientific eye, unconnected with each other, are shown to be only links in a continuous chain of cause and effect. In some cases science seems to act by a kind of contrary motion; she pushes the object of our investigation farther from us than ever with one hand, while with the other hand she gives us the instrument that will enable us to bring it nearer than ever. With the parallax measurement she thrusts the fixed star into gulfs of space which can only be measured by the time occupied by the passage of their light to us: with the spectrum analysis she shows us nevertheless how that light can bring, after its enormous journey, information as to the chemical constituents of the body from which it emanates. This was one of the points touched upon in Sir John Lubbock's address as an example of the danger of limiting the powers of scientific investigation, since no less a man than Comte, as we had ourselves pointed out a fortnight ago, had assumed as a matter of course that of the chemical composition of the heavenly bodies "we could never know anything." Taken altogether, the retrospect of the last fifty years suggested by the President at this meeting of the British Association offers a wonderful and entrancing spectacle of what it is within the powers of man to understand and discover, and suggests ideas as to what the future may accomplish to which it is difficult to assign any limit; and those who imagine we live in a worn-out and uninteresting period may rest assured that they are either looking the wrong way or looking with their eyes shut.

We must descend, however, from the general to the particular in order to notice some of the special points which have been touched upon during the meeting that has just been held at York. We have already referred to Sir John Lubbock's address, which was a clear and concise survey of the scientific progress of the last fifty years, bringing out more in detail some of the remarkable steps in scientific knowledge to which we have referred in a necessarily cursory manner. The subjects touched on successively as those in which great steps have been made were partly of purely intellectual, partly of practical value. The "origin of species," the greatest step in natural science since the time of Newton certainly, was first referred to, and one or two of the popular fallacies in regard to it corrected. Then was passed in review the remarkable light thrown on the question of disease and its cure by the germ-theory of the development of disease, which grew, curiously enough, out of researches in reference to what most scientific men believe to be an entirely groundless theory,—that of spontaneous generation. The experiments made in this direction have had the result of destroying for the present all

the supposed grounds of belief in spontaneous generation, and at the same time, also, have had the very important result of bringing to light a great deal of unspontaneous generation where it was little suspected before, and of leading us to regard many diseases certainly, and all probably, as the result of vegetable or animal growths of a very minute nature, which may be destroyed by finding out and inducing conditions in which their deleterious life cannot be supported. Already some physicians, too sanguine perhaps, are talking of a not far-distant period when disease, no longer regarded as a kind of mysterious visitation of Providence, but as a parasitic growth possible only under certain ascertainable conditions, shall be "stamped out." Then from our own individual being we were invited to consider the structure and what may be called the diseases of the "*Grand Etre*," as Comte fancifully called the earth: a subject which was treated of more in detail afterwards in one or two sectional papers. From the earth it was a natural transition to the other bodies, among whom it plays a very insignificant, though to us all-important, part; and from astronomy again to the question of the meaning and composition of the light by which alone we are conscious of their existence. Here the President touched upon a subject which has much interest for many of our readers, the composition and relation of colours; and it may interest some of our correspondents who wrote to us not long since on the subject of colour, to know that as long ago as 1792 the common idea that red, blue, and yellow are "primary colours" was contradicted by Wünsch, whose theory is now generally accepted by scientists in colour, though long neglected; and Sir John Lubbock did not fail to emphasise the distinction, so entirely ignored by many, between colours and pigments, and to show that because blue and yellow pigments made a green pigment, it by no means follows that blue and yellow rays of light produce a green colour, which, in fact, they do not; and this part of the presidential address may afford to people who are sad by reason of the disrespect thrown upon their ancient and respectable theory of primary colours, some hint as to the direction in which to seek for scientific truth in a matter so interesting, theoretically, if not practically, to those whose business or profession it is to "lay the colours on," as we once heard an eminent painter describe his trade. Running over rapidly the principal practical scientific inventions of the half-century,—a remarkable list in themselves, and which could only just be touched upon,—the President summed up in claiming lastly for science that it had evolved and brought into being the very idea of "progress," which he affirmed was unknown to the ancients, and was only due in modern times to the mode of thinking induced by science. To this we must demur, as one of those too comprehensive generalisations sometimes made by scientific men, who look at all things in heaven and earth from a too exclusively scientific point of view. There is no doubt that the idea of the Darwinian theory has given a great impetus to the conception of a possible continual upward progress of the human race from higher to higher knowledge, and that this idea is more prominent in the minds of men just now than it ever has been before, owing to the enormous vistas of possible discovery with which modern science has dazzled them. But we certainly are not in a position to say that the idea of progress was unknown to the ancients, or that a people who, like the Greeks, rose steadily through imperfect forms of art to the most perfect that has ever been seen, had not the conception of progress. But then progress in art, we fear, your true scientist thinks very little of; and that is just one part of the narrowness of the scientific mind,—not a petty narrowness, but a narrowness (if we may so say) on a great scale, against which those who are dazzled by the great power and aspirations of modern science need to be on their guard, remembering that, after all, scientific knowledge and acquirements appeal only to one-half of the human mind, and cannot in themselves satisfy a complete and imaginative nature. But that is just the mistake the prophets of science make, and for which another generation will probably to some extent take its revenge on them.

In glancing through some of the sectional subjects, and the suggestions involved in them, we take note here only of those which bear more or less on the practical subjects which are of special interest to ourselves. Artistic subjects, equally interesting certainly to us, do not, of course, come into the programme of the British Association. First among these subjects we come on Sir W. Thomson's address, as President of the Mathematical and Physical Science Section. This was a brilliant, — may we add, somewhat sensational?—*resumé* of the position in regard to available powers for driving mechanism. Coal, we were again told, was getting rapidly exhausted, though we cannot help thinking it has a longer lease before it than some authorities are willing to allow; rain-storage is entirely delusive as a means of accumulating power in any economical form; electric power is the power of the future,—all we want to work it is a cheap motive power, if possible utilising some natural and permanent force in nature. Cheap windmills, Sir W. Thomson thinks, we shall want, though he admits that wind is a somewhat uncertain agency,—more so, he seems to think, than formerly; and special means to supply the batteries would have to be provided for use in the event of calms. But another suggestion is to utilise Niagara for a large area,—say 300 miles round the site of the falls,—for supplying the power to drive powerful and numerous batteries for lighting the world by electricity. There, certainly, is an enormous power lying unused except as a spectacle. But what a chorus of complaint and objurgation would rise up at any serious proposition to turn Niagara into a huge mill-shoot. We doubt if public opinion would allow it to be done, and we can hardly say that we should not be on the side of public opinion; however, we do not anticipate being called upon to assist public opinion on the subject either one way or the other for a considerable time to come. The President of the Mechanical Section, Sir W. Armstrong, dwelt chiefly on the same subject, the utilisation of electricity, not merely in lighting, but as a mechanical power. The idea suggested chiefly in Sir W. Armstrong's address * was that of the possibility of converting the sun's heat into electric energy, which would give us an almost unlimited stock of power whenever the apparatus is forthcoming to produce the conversion. Until then, we must be content to use electricity for the most part not as a prime force, but as a result of force, or a means of conveying it; and in this connexion we observe he also speaks of the time when we shall have commenced the utilisation of waterfalls for this purpose as a time certainly coming and in fact not far off. We will not say that the result may not work for the greatest happiness of the greatest number, in which case its accomplishment, if materially practicable, is certain to follow sooner or later, but we cannot repress a feeling of sympathy with the many people who would feel keenly the transmutation of all the waterfalls into "powers." Their use in this way, however, and still more the conversion of the sun's heat into electric force, if it were ever accomplished, would at last be the realisation, practically, of the old baseless dream of "perpetual motion," though in a different sense from that in which it was sought for by the dreamers themselves. Persons who are sensitive on the subject of the English climate may be amused at the idea of evolving anything like "perpetual" motive power from the heat of the sun in this country; but it must be remembered that we should now be able to calculate, or at least it seems probable that we should, on the transmission of power to great distances, not only by the electric current, but by the farther development which may be expected from Faure's accumulator as a facility for the storage of "force."

The utilisation of the electric light, which meets us at every turn and in every form at present, was further illustrated in what appears to be an already practically realised success, in the interesting account given by Dr. Siemens in his paper communicated to the Physical Science Section. This was a description of his experimental introduction of electric light in his own greenhouses, with the view of ascertaining whether the lighting up of the plants with this light between sunset and sunrise, imitating as far as possible the effect of continuous sunshine, would promote more rapid and fuller growth. The results, according to his account, are exceedingly remarkable and unexpected. It would be the natural conclusion, we imagine, of most people, that the interruption of the regular recurrence of darkness would be such a violen change from the general conditions of vegetable growth as to be injurious rather than beneficial. And it appears that in the first instance the effect of the naked light on the plants was decidedly injurious, and the plants soon showed a withered appearance. One attempt to reduce the direct effect of the light was by introducing into the house jets of steam drawing atmospheric air with them, and thus imitating the effect of interposed and passing clouds. This effected an improvement, but subsequent experiments showed that a still better result was obtained by merely interposing a sheet of clear glass between the light and the plants, and that under these circumstances the plants throve remarkably, and, in fact, abnormally. So marked was the effect of the glass that when a small sheet was interposed so as only half to screen a plant from the light, the line of demarcation between the part illuminated by the naked light and that screened by the glass was distinctly visible on the leaves of the plant. This seems to show that the deleterious effect of the light was chemical; but to us the interest of the experiment lies in the conclusion which it seems to point to that, recognising the strong analogy between life and growth in plants and in animal organisms (indeed, modern science hardly draws a line between them in some respects), the far greater use of strong artificial light such as the electric light need not in the end be expected to produce any ill results on human life; and, in fact, that the idea of the necessity of periods of darkness is a habit which may be broken through with a little effort without injury to organic life. As we do not yet know to what lengths the use of electric light may eventually be carried in turning night into day, it is certainly very significant to find that plant life, at any rate, seems rather to gain than to lose by this change of its conditions, extreme as it seems. It would be strange if science were in the end to lead to the practical conclusion that such an important procedure in nature as the alternation of light and darkness on our planet was after all no essential condition of healthy life, but a kind of prodigious accident, the loss of which would leave us in reality little altered! The necessity in animal life for regularly recurring periods of rest would of course remain. In the mean time the practical results in regard to vegetables seem to be actually appreciable in more rapid and luxuriant growth and therefore more economical use of the greenhouse. Where may, or, rather, where may not, this end? Already Dr. Siemens hints at the possibility of the gardener actually having, practically, the alteration and variation of the seasons at his command. The possible (may we not say, highly probable?) part to be played by electricity in the locomotion of the future was strongly emphasised also not only in Sir W. Armstrong's address before referred to, but in one by Sir F. J. Bramwell on the developments of mechanical engineering during the last fifty years. He concluded by referring to the steam engine as already almost a thing of the past, and doubted whether those who would meet fifty years hence would find them except in museums. There is unquestionably, however, a good deal to be done before a locomotive agent so swift, powerful, and tractable as the locomotive engine of to-day, will be realised in any other form.

We may conclude by reference to a paper which, though dealing with a much smaller subject than those we have been referring to, touches especially on our province. This was Professor Owen's address as President of the Zoology and Botany Department, which consisted of a full and very racy account of the initiation and subsequent history of the National Natural History Museum. The story told by Professor Owen is instructive in regard to what may be gained by resolutely sticking to one's point even against apparently hopeless odds. Professor Owen's large scheme, demanding a site ten acres in extent, was condemned not only by a Parliamentary Committee (which would not go for much), but by a number of the most eminent scientific men of the day, the Professor standing quite alone in his recommendation of the scheme. The objections to it were partly economical, partly due to a theory, perhaps to some extent founded on the other objection, that so large a collection was only bewildering and cumbersome, and of no real use for purposes of instruction. Professor Owen has now, however, got, if not his ten acres, at least eight of them, and he may rightly feel gratification in remembering, as he

* The pith of this paper, and of others most likely to interest our readers, we print on other pages.

says, that his sole responsibility for the scheme is recorded, though in expressions more terse than complimentary, in the pages of that voluminous publication which, he suggests, may outlast the organisation of the body whose debates it records. In the course of his address Professor Owen spoke with admiration of the thorough manner in which Mr. Gladstone went into the question when it came before him while in office, going personally into every corner of the department in the British Museum, cellars included, and seeing everything for himself; and he also expressed very warmly his praise of the new building and of the ability shown by Mr. Waterhouse in its arrangement and architectural treatment, in which few of our readers will disagree with him.

Electricity, however has been the central subject of this meeting of the Association, which has been a very brilliant and interesting one, and which suggests far more topics for reflection and expectation in regard to the future than we have been able to touch upon here. To some of these we may return.

1881: A GREAT CENTENARY FOR ENGLAND.

THE celebration of centenaries is a habit which, in many cases, would to our mind be better honoured in the breach than in the observance,—the link between the lapse of a century and the event commemorated as being a century old being usually one of a purely arithmetical order. The year 1881, however, observed or not, is a centenary of the first importance to England. The present year marks the close of the first hundred years of the actual existence of that invention which has done more, not only than any other, but than all others, to revolutionise the relation borne by man to the planet which he inhabits. "In 1781," said Sir John Rennie, in his address to the annual general meeting of the Institution of Civil Engineers on the 20th of January, 1846, "Watt invented the means of producing rotary motion by the steam-engine, first by the crank, and afterwards by the sun and planet wheel, thus rendering it applicable for the purpose of driving all kinds of machinery, which was a grand step towards the improvement of manufactures." In fact, this simple and beautiful invention has been to the steam-engine, generically, what the blast has been to the locomotive, specifically. It has supplied the one practical link between the source and the application of motion, without which mechanism would have been imperfect and clumsy. For the honour of inventing the steam-engine there are many claimants. In 1698, it was first rendered, by Savery, an efficient means of raising water. In 1712 it was actively employed for that purpose, by means of a steam cylinder, into which cold water was injected for forming a vacuum, so as to enable a movable piston to be impelled by the pressure of the atmosphere, to which, by the use of a lever, a pump for raising water was attached. In 1713-8 this pump was so improved as to be made self-acting; but the consumption and expense of fuel were so great that its application was very limited. But while Watt, from 1777 to 1782, was perfecting his idea of the application of steam, with expansion and with double action, above and below the piston; while, in 1784, he invented the parallel motion, working gear and valves, the governor, and other important details, which were brought together in the machinery for the first steam mills, the Albion Mills, in 1784,—the inland navigation of England was being adapted for the distribution of fuel, at low prices, in every district that was served by a canal. In 1758 Brindley was withdrawn, by the Duke of Bridgewater, from his occupation as a millwright, for the purpose of executing the Bridgewater Canal. In conjunction with Smeaton and others, he subsequently executed, with great success, the Trent and Mersey, the Leeds and Liverpool, the Birmingham, and the Forth and Clyde canals: works that remain as lasting monuments of his skill and genius in this branch of the duties of the civil engineer. Our canals had only been dug to an aggregate length of about 4,000 miles (4,138 we make to be the nearest approximation to exactitude that is obtainable), when the railway companies began to struggle for a traffic which they had far better have left to the canals. At the present time, 1,716 miles of canal have been purchased, leased, or otherwise acquired by the railway companies, which have now obtained the command of the inland coal traffic; although the open highway of the sea has happily prevented the existence of the monopoly sought for by the struggle.

The opening of our coalfields was the immediate result of the creation of our canals. The ready and cheap transport of coal gives to the steam engine that food on which its economic value depends. The average consumption of coal, per indicated horse-power per hour, in steam ships with compound engines in long sea voyages, averages 2·11 lb. (Manual of Rules, Tables, and Data for Mechanical Engineers, p. 889). The performance of some of the most powerful railway locomotives has been measured as 2·28 lb. of coal per horse-power per hour, ascertained by load and speed. The gross work done on a piston by 1 lb. of steam varies, in round numbers, from 56,000 to 62,000 foot pounds, equivalent to from 72 to 80 units of heat. This work rises, by the use of expansion, to as much as 150,000 foot pounds, when expanded about six times, and cutting off about 10 per cent. of the stroke. Even under the most favourable circumstances, only 20 per cent., or one-fifth part, of the heat consumed is converted into work. The highest duty recorded in the Cornish mines, where great attention is paid to this subject, was 108,000,000 pounds lifted 1 ft. high by the consumption of a bushel of Welsh coals, weighing 94 lb., at the United Mines, in 1842 This is equal to nearly 1,149,000 foot pounds of work done by the consumption of 1 lb. of coal. Taking this as a result possible with the best fixed machinery under the most advantageous circumstances, and comparing it with the former result of about 2¼ lb. per horse-power per hour applied to locomotion or navigation, it is evident that one quarter of a cwt. or 28 lb. per horse-power per day of ten hours, is a very attainable result for a good steam-engine. At 300 working days per annum this is equal to 3·75 tons of coal per horse-power per year. To allow for waste and mismanagement, let us say five tons. The average price of this, at the pit's mouth, is from 5s. to 7s. per ton, or a mean of 30s. plus the cost of carriage of the fuel, for the cost of a horse-power for a year.

It was estimated by Mr. Cossham, a coal-owner of experience, in 1877, that 23·50 per cent. of the coal raised in Great Britain was used in raising steam for manufactures, and another 4 per cent. for steam and railway locomotion. Returns of the coal raised do not go back further than the year 1854, when the total output was 64,660,000 tons. From the proportion borne by the product of the South Wales coal-fields, of which the yield in 1800 is known, to the whole produce of the United Kingdom, we estimate the yield of 1800 at 16,666,000 tons. At that time, however, the allowance for steam-locomotion and navigation was not required. For manufacturing purposes alone, Mr. Cossham's rule would give a consumption of 3,915,000 tons of coal in 1800, and our rule would make this represent a force of 781,000 horses. In 1879 the out-put of our collieries is returned at 133,800,000 tons. The proportion assignable to steam-power is 36,795,000 tons. The equivalent power developed is that of 7,359,000 horses.

Such, then, is an approximate statement of what the genius of the engineer has done for England. If we name James Watt as the foreman of the goodly company in which Smeaton, Brindley, Telford, George and Robert Stephenson, Mark and Isambard Brunel, and so many others, have been fellow workers, it is not with the idea that merit can be thus personally distributed. If we speak of the birthday of the Crank, it is only as one of the simplest and most beautiful details, mechanically speaking, which have been combined to allow of the present wonderful organisation of the steam-engine. With that reserve, the centenary of the birthday of the crank is one of the most important that has ever occurred in the annals of England. It measures a century of progress such as the world never saw before. And it commemorates an invention which has placed at the service of England,—a service not negligently exacted or performed,—a force greater than that which could be exerted by seven millions of horses.

It would be of great national service to obtain a census of the steam engines of England. The only element for such a statement which exists is the return of railway locomotives. In 1879 there were 13,174 of these engines on the railways of the United Kingdom. A powerful passenger engine, on the Great Northern Railway, was stated, in a discussion at the Institution of Civil Engineers, on the 11th of November, 1873 (see vol. xxxvii. of the Proceedings), to do the work of 678 horse-power. It is not usual to state the work of the locomotive in horse-power, as so much depends on the speed at which it is driven. But if we take less than half the Great Northern power, say, for the sake of simplicity, 333 horse-power per locomotive, we find these machines to represent a power equal to that of 4,386,942 horses. That, of course, is a statement not of work done by them, but of the work which they are able to perform, if all at work at the same time, and to keep up, if supplied with fuel, burning rather less than 28 lb. of coal to the mile run.

As to the actual horse-power of our steam fleet, no returns exist. There is, moreover, a very great difference between the nominal horse-power and that at which the same engines are capable of being worked. Thus, the *Scythia*, one of the Cunard line of packets, with a builder's measurement of 4,566 tons, has compound direct-acting engines of 600 nominal horse-power, which are capable of being worked up to five times that amount, or 3,000-horse-power. In our war fleet, where great speed is required, the indicated horse-power is at times as much as or even more than 1-horse-power per ton. The *Plucky*, a little vessel of 198 tons displacement, has a steam power of 224-horse power. The *Pickle*, of 254 tons, has 268 i. horse-power. Among the larger vessels, the *Agincourt*, with a displacement of 9,071 tons, has a steam-power of 6,867-horse-power. The *Inconstant*, with 5,328 tons displacement, has 7,361-horse-power. The *Sultan*, with 8,714 tons displacement, has 8,629-horse-power. The *Hotspur*, a twin-screw vessel, with 3,980 tons displacement, has 3,497 i. horse-power. Mr. Clement Mackow, in his excellent "Naval Architect's and Shipbuilder's Pocket-book," gives a table of the co-efficients of performance of fifty of her Majesty's screw vessels. Of the eleven items which are tabulated, there is but one column in which anything like regularity is maintained. That is the column headed $\frac{V^3 \times D^{\frac{2}{3}}}{H}$ by which formula is signified the cube of the velocity, multiplied by two-thirds of the displacement, and divided by the indicated horse-power. But the values even in this column vary from 94·9 to 289·6. If we take the figures 175 as a mean for this column, we find that for a mean speed of ten knots per hour, 380 i. horse-power are required for every 1,000 tons of shipping. The total number of steam-vessels registered as belonging to the United Kingdom at the end of 1880 was 5,247 (or four times the number of the locomotives on the railways), with an aggregate tonnage of 2,723,468. The approximate rule which we have ventured to formulate, and which we think will be rather under than over the mark, makes the steam-power required for this tonnage amount to a force of 1,033,000 horse-power. But there can be but little doubt that if the method adopted by Mr. Robinson were applied, and if the actual resistance overcome by the steam fleet were calculated in horse-power, we should arrive at much larger figures. According to the Navy List, the Royal Navy contains 993,748 tons of shipping, N.M., and 679,473 H.P. The combustion of 3,000,000 tons of coal, which is probably a low estimate for the coaling of the mercantile navy, would represent a force of 600,000 horses,—but one in constant exercise for ten horses per day, and for 300 days in the year. The difference between the potential and the actually exerted steam-power of steam-vessels, as well as of locomotives, is enormous; and the same may be said with reference to the vast stationary steam-machinery of the country, the estimate for the coal consumed by which, in 1869, was nearly six times as much as that required for the purposes of navigation and railway locomotion.

The Coming Social Science Congress.—As already announced, this year's Congress of the National Association for the Promotion of Social Science will be held in Dublin from the 3rd to the 8th of October. The Right Hon. Lord O'Hagan, Lord Chancellor of Ireland, will be the President of the Congress. The President of the Health Department will be Dr. Cameron, M.P., while the Right Hon. Viscount Powerscourt will preside over the section devoted to the discussion of Art questions.

BUILDING AND DECORATION IN VIENNA.

In our last notice on building in Vienna,* we omitted mentioning the progress of the new Palace of Justice, an edifice the erection of which was commenced as early as 1875, and which is now rapidly approaching completion. We gave some particulars of the building, together with an interior view, in the *Builder* of September 14, 1878, and we are now able to furnish some additional details, more especially with respect to its decoration.

The estimate of the architect, A. von Wielemans, is three million florins (250,000*l.*). The building is to receive the supreme court of justice, the court of appeal, the court for civil cases, and the tribunal of commerce. The vestibule will have a height of 29 ft. 6 in., and its ceiling will be supported by twelve columns of Untersberg marble. This entrance leads into a central hall of rather gigantic dimensions, being 82 ft. high. The public courts are in the first story. The lobby of the supreme court is a hall 98 ft. 6 in. long, round which are offices. The plans for the new *Justizpalast* were exhibited in the summer of 1874, the designs being in all possible and impossible styles of architecture. The jury selected that of Wielemans, a young and until then little known architect (one of the most talented disciples of van der Nüll, Sickardsburg, and especially of F. von Schmidt, the cathedral architect), who was finally entrusted with the direction of building operation in September of the same year. The colossal edifice, the foundations of which, as we have already said, were begun in 1875, and which is one of the best architectural monuments of Vienna, is now nearly completed in all its details, and covers an area of 93,000 square feet. The architect selected the German Renaissance style, embellishing his work by a wealth of interesting details, the whole conception testifying to considerable genius. The portico is reached by fiers with convenient ascent, on the flanking pedestals of which sculptured lions will ultimately be placed. The principal façade of the two-storied building is marked by a powerful pediment and two turrets. Over the principal portal, in the pediment, a colossal figure of Austria, by Helmer, is placed, in effective contrast to the dark background of the niche in which it stands. The free space in front of the Palace of Justice is unfortunately of a trapezoid form, but it is intended to mask this eyesore by suitable garden grounds.

The interior of the building is full of well-conceived and tasteful architectural and decorative details. Amongst these may be mentioned the pedestals of the columns, richly sculptured by Pokorny, as well as all the lanterns, candelabra, door-railings, balustrades of wrought iron, the splendid oak doors, wooden panels, &c. It is soon perceived that everybody engaged in the work has tried to do his best. The art industries of Vienna have shown on this occasion what they are able to perform; but it should be mentioned that the architect has been ably assisted by coadjutors, such as the Cologne architect Dominik Asanzo, the engineer Arthur von Wielemans, and others. If the exterior of the edifice appears clearly and well defined on the whole as well as in detail, the interior is well lighted in all the rooms and convenient in its communications. We proceed now to describe the principal rooms.

The vestibule is carried through two stories, and is a splendid space, with a ceiling supported by columns. The shafts are of reddish Salzburg marble, the bases being in Grusignano marble richly carved. The centre of the ceiling is adorned by a slab, carried by two decorative supports, with the inscription "Justitia regnorum fundamentum" (the well-known motto of the Emperor Francis I.). Next to the vestibule is the great central hall, also a grand room, carried through all the stories of the building, which explains its great height of 82 ft. before mentioned. The soft shades of the painted-glass ceiling harmonise pleasantly with the various colours of the marble and granite. The arcades of this hall, which is, properly speaking, a court, are supported by handsome square pillars on the ground-floor, in the first story by columns of red Pavenno granite, the second story being a mezzanine. A principal object in this hall is presented by the stairs facing the entrance, with steps of Salzburg and balustrades of Trient marble, the latter with open-work ornamentation. In the spandrels of the first gallery the coats-of-arms of the Austrian crown-lands, carved and coloured, have been inserted. Above the stairs, in a niche flanked by double columns and surmounted by the imperial coat-of-arms, a symbolic female figure, 10 ft. high, and representing Justice, has been placed. It is in Laas marble, and is the work of Pendl, a Viennese sculptor.

These stairs lead to the principal courts in the first story, and to all the other rooms. The most remarkable one is the great court, carried through two stories. The funds for the frescoes, to be painted by Professor Eisenmenger and Julius Berger, have not yet been provided, and thus the "Functionssaal," as it is called, is devoid of all ornamentation, and will be used for a little while in its present white garb. The busts of the Austrian Emperor and Empress are the only decoration of the room. They were presented by the Vienna Chamber of Advocates. At the back of the principal stairs is the Advocates' Hall, which contains a handsomely-carved ceiling and wainscoting in the German Renaissance style. The fittings of the room, desks, tables, chairs, &c., though richly carved, are in keeping with the whole character of the edifice. The so-called "Plenissimum," or principal hall of the supreme court, is perhaps the most splendidly-decorated room of the building. It also has a carved wooden ceiling, in the centre of which an imperial eagle, 10 ft. in diameter, extends his wings. A frieze, painted by Jobst, and containing a series of portraits of Austrian emperors, runs round the room. Above the judge's seat, opposite the entrance, is the portrait of the present emperor, painted by Berga. The library, containing 10,000 volumes, is to the left of the supreme court. It has likewise a carved ceiling, a gallery of wrought iron, and neat desks and book-cases with brass screens. To the left of the library is the principal room of the court of appeal, adorned like the Plenissimum. The remaining public courts are arranged and fitted up on similar principles.

There remains yet to be mentioned the great lobby in the outer wing of the building, facing towards the Reichsrathplatz. Its ceiling is supported by double columns of grey Karst marble; its frieze bears the imperial family arms; over the entrances to the different courts have been placed such judicial emblems as sword, scales, fasces, &c.; marble tablets display the names of all chief judges, or judge-presidents, from the time of Maria Theresia to the present reign. On the occasion of laying the foundation-stone, which took place quite recently, after the building had been far advanced, the various speakers were full of praise respecting the new palace of justice, by the erection of which the Austrian capital has acquired another highly artistic and monumental edifice. Its builder, Alexander von Wielemans, has by his work at once established a reputation as one of the foremost architects of the Continent.

When we spoke of the progress of building and decoration in Vienna last, it was stated that the carriage approach to the new Houses of Parliament, as originally planned, would have to be abandoned. We now learn that the matter has been satisfactorily settled. Without trenching upon the area of the Ringstrasse, to be avoided at any cost, the approach will have a rise of about 1 in 20, and end in a semicircular terrace and stairs leading to the entrance. The approach will be brought out to the Ringstrasse, the level of the terrace lowered, and the entrance to the portico gained by stairs of seven steps. A large monumental fountain is to be placed in front of the approach and terrace.

Another matter of interest in Viennese art circles is the enlargement of the "House" of the Vienna Society of Artists, which was recently unanimously resolved upon at a general meeting of its members. It is believed that 250,000 florins will cover all building expenses. The society's house is to be extended towards the garden, of which a portion will be appropriated. Provisional plans have been prepared by the architects Streit and Schacher. It is proposed to erect a one-story building, joining the two back corner pavilions, and forming a parallelogram facing the Lothringer Strasse. A small court will be provided in the centre of the new wing. The Künstlerhaus will gain by this addition two rooms, lighted from above, each 85 ft. 6 in. long, 21 ft. 6 in. wide, and 20 ft. high, with a wall-space of about 4,300 square feet, and two galleries containing a wall-space of about 1,800 square feet each. The court will have two loggia for the reception of sculpture. When the project of the extension became first known, it seemed as if the owners of surrounding property would prove troublesome. But it was soon found that, even if the enlargement had included an additional story,—the old building is only two stories high,—the proposed addition would not have interfered with their outlook. Besides, any addition made could not well exceed the original height without spoiling the leading idea of the designer of the Artists' House, the late architect Weber. The enlargement has become absolutely necessary. When the House was first erected, it was thought that ample room had been provided for all emergencies; but since international art exhibitions have become the fashion, this supposition has proved to be fallacious and the space at disposal quite inadequate for such extended exhibitions.

Some life has recently been imparted to the building operations at the new University, which at one time seemed almost to have come to a standstill. They are proceeding now more actively; and although the building is still far from having assumed its final form, one is able even at this point to say that it will be a splendid edifice. Carved work and sculpture is making its appearance here and there; but the principal part of the adornment is awaiting execution. The courtyard of the University, with its arcades in the high Renaissance style, will be one of the largest and handsomest courts of the new buildings of Vienna. The walls of the arcades, simply ornamented, are in Groisbach stone. In the courtyard itself a monumental fountain will be placed. The arcades will receive frescoes, surrounded by rich stucco frames, and representing the development of the sciences. Several other spaces,—for instance, the vestibule, staircase, &c.,—will receive stucco work. The execution of the latter, and of all details, will be proceeded with slowly and piecemeal, so as to test their effect before completing the whole. The plastic decoration generally will be in various materials, stone, terra-cottas, and majolica. The statuary will be in the first-named material; the figures in the spandrels are to be in terra-cotta, the medallion portraits of majolica, white and blue with gold framing. Above the great pediment of the principal façade the figure of Nike or Victoria will be placed; in the pediment itself the birth of Athene (Minerva) is to be represented. The latter subject will be treated by Professor Tantenhayn. In the attics of the pavilions are to be placed figures representative of Medical Science, Jurisprudence, Philosophy, Theology; next to them will be ranged subjects representative of special branches of science, such as biology, civilisation, Bible study, &c. The side façades will be adorned by statues of mythological personages, amongst them Hermes (Mercury), Thalia, Apollo, Clio, Gæa, Neptune, Prometheus, Urania, Orpheus, &c. In the niches of pavilions of the first story the following figures will be placed:—Plato, Artistotle, St. Peter, Moses, Solon, Justinian, Hippocrates, Galenus, Charles the Great. The medallion-portraits will be those of Pliny, Erasmus, Descartes (Cartesius), Leibnitz, Newton, Galileo, Copernicus, Kepler. The tablets will contain the names of Kant, Lessing, Winckelmann, and other well-known names. Amongst the artists who will execute those works may be mentioned Rud. Weyer, Wagner, Jos. Gasser, Edm. Helmer, J. Berger, David, Silbervogel, &c. It is said in praise of the building that it will, when completed, display a harmony of architecture and the decorative arts seldom to be met with.

As if Vienna had not theatres enough already, another is to be added to the large number of playhouses possessed by the Austrian capital. Only three of them (of which two receive subventions) pay at all; the others eke out a precarious existence. But the latest addition, plans of which have already been prepared, and which is to be placed in the growing suburb of the "Landstrasse," is to be something quite out of the common. In its interior it is to resemble the well-known "Théâtre Eden," Brussels, and will combine within it winter gardens, refreshment rooms, lobbies, galleries, atria, loggias, &c. A peculiarity of the new theatre will be that from all these various places the performance may be witnessed. The promoters are an Antwerp Company, and the theatre is to be named the "Théâtre de Vienne." The plans have been prepared by the architects Wilhelm Kuhnen (the builder of the Théâtre Eden, Brussels) and Wilhelm Stiassny (Vienna). The building will

* See *Builder*, vol. xl. (May 21, 1881), p. 626.

have a length of 279 ft. and a width of 197 ft., and will be especially constructed and fitted up for the performance of sensational and historical pieces, transformation scenes, ballets, &c.

THE RIGHTS OF VENDORS AND PURCHASERS OF BUILDINGS IN REGARD TO EXISTING FIRE POLICIES.

IT is a curious fact that points of a comparatively elementary and everyday kind in regard to the law, which, it might naturally be supposed, would have long ago been settled, are continually cropping up. It is so in regard to this question of the rights of vendors and purchasers of buildings with reference to existing policies of fire insurance. To those who are concerned with buildings professionally or as investments few questions can be more important, and we confess that it is a matter for regret that in regard to one special and interesting point it is impossible to consider the subject as being in a thoroughly settled state. It may be well, first of all, to point out that, as a general rule, a purchaser does not get with the property any policy of insurance which exists upon that property; about this there can be no doubt, as the policy is a contract between two persons, the rights under which cannot be conveyed to another without an express agreement to this effect.

But the immediate question is not quite so broad as this, but it arises in this way: An agreement for the sale of a house is duly entered into, but, as usually is the case, a certain time is to elapse before the actual conveyance is executed and the purchase-money is paid to the vendor. If at the time at which the completion of the matter should take place, the purchaser is ready with the money, but the vendor will not complete his conveyance, the Chancery Division will, as many of our readers are aware, enforce the fulfilment of the agreement. But let us suppose that between the date of the agreement and the time for the completion of the bargain the house is burnt, and that there is an existing policy of insurance on it, and that the vendor receives the amount due from the insurance company. These are the facts which actually occurred in the recent case of Rayner *v.* Preston (50 *Law Journal*, Chancery Division, p. 472), a case which gave rise to much discussion both before the Master of the Rolls and the Court of Appeal.

Under such a state of things as this, the question,—one which it will be immediately perceived is of great practical importance,—arises, Does the vendor hold this money recovered from the insurance company for his own benefit, or is he bound to hand it over to the purchaser? In other words, does he receive it as a trustee for the purchaser? Having regard to this last case, it must be answered that the vendor may keep the money himself, and leave the purchaser the pleasure of repairing the damaged premises out of his own pocket. This was the conclusion arrived at not only by the Master of the Rolls, but by Lords Justices Brett and Cotton, as against the late Lord Justice James, who was of a contrary opinion. But, having regard to the great judicial value of the late Lord Justice James's opinion, it cannot be said that the law is in a thoroughly settled state, although a lawyer could give a confident opinion that until this case is reversed by a higher tribunal it is binding on any inferior court. And while upon this point, it may be well to point out that an unpaid vendor may recover from the insurance company; but whether, if the money were not expended on the building, he could keep it as against the company, is a matter of doubt, for after the judgment in the case of Rayner *v.* Preston had been delivered, Lord Justice Brett remarked, "I should like to add to what I have said, that I feel very considerable doubt indeed whether, as between the defendants (the vendors) and the insurance company, the defendants (the vendors) can keep the money." And in this doubt Lord Justice Cotton concurred.

Upon the main question, however, with which we are now chiefly concerned, few can doubt that in natural justice the purchaser should have the benefit of the money which the vendor recovers, and there is great force in the remark of Lord Justice James that "the policy of fire insurance is not a wagering contract,—a contract that if a fire happens then a certain sum shall be paid to the insurer; it is in terms and in effect a contract that if the property is injured the insurance company will make good the actual damage sustained by the property. That damage, and that damage only, gives the right, and is the measure of the right, to recover from the company." And the late Lord Justice, at the conclusion of his judgment, thus succinctly summarises his general opinion on the question,—"The relation between the vendor and purchaser was in law as from the date of the contract the relation of trustee and *cestui que trust*, and the trustee received the money by reason of and as the actual amount of the damage done to the trust property." But though our sympathies may go with the dissentient Lord Justice, it is difficult to overcome the reasoning of the other judges, who point out that the contract between the vendor and the insurance company was a purely personal one for the payment of money on the happening of certain conditions. Further, Lord Justice Cotton states, "the argument that the money is received by virtue or in respect of property which is trust property is, in my opinion, fallacious. The money is received by virtue or in respect of the contract of insurance, and though the fact that the insured had parted with all interest in the property insured would be an answer to the claim, on the principle that the contract is one of indemnity only, this is very different from the proposition that the money is received by reason of his legal interest in the property." It would be presumptuous for us when such able and distinguished lawyers are divided upon this question, confidently to give our opinion. But we confess that we are inclined to side with the majority on this occasion; nor do we know that the purchaser is so very much entitled to our sympathies for not getting the benefit of the policy existing on the buildings. For let us point out these facts. If there had been no contract of sale in existence, and the owner of the house, having received from the insurance company the amount of the damage done to the building by fire, had chosen not to reinstate it at all, or in a way which cost half the amount he received from the company, he would have been entitled to pocket the whole of the difference. The insurance company would not compel him to build up his house again if he preferred to have the money. Let us also suppose that there had been no insurance existing in the present case, and that the house was damaged to the extent of 500*l.*; the purchaser would have had to take it damaged to this extent, and worth less by so much than when the contract was made, without getting any corresponding diminution of the purchase-money. That being so, why should the mere chance of a policy existing place him in any better position as regards the vendor of the house, and why should the latter not exercise the option which he before possessed of keeping the money in his pocket or of repairing the house? It is true that no right-minded man would hesitate to hand over the sum received from the company to the buyer; but, looked at without regard to feelings, what right has the buyer to expect the seller to make him a present of this windfall, for such it would be to the vendor? If the purchaser wishes to be safe, he should make an express stipulation with the vendor that he shall have the benefit of any existing policy upon the buildings which are the subject of the contract. And the moral for practical men of business which is to be drawn from this decision is, that in all cases the purchaser should stipulate for the benefit of any existing policy, and, if the building is not insured, should insist that the vendor shall take out a policy of which the purchaser shall have the benefit, and then the latter will be in a perfectly safe position.

SAVE THE CORN!

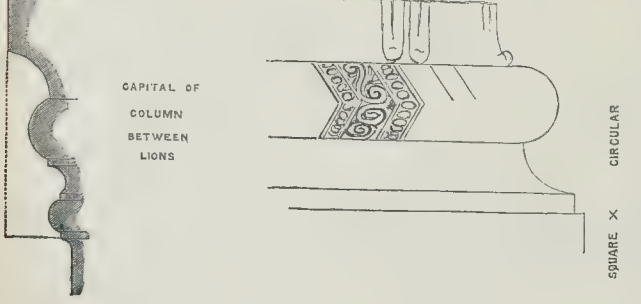
COLONEL COXON in the *Times*, and another writer in the *Morning Post*, are reproducing a suggestion which we made some years ago in the *Builder* as to the desirability, in very wet seasons, of saving at least the ears of corn, leaving the stalks for treatment when weather would permit. Our own proposal was rather fiercely combated by a correspondent who spoke as a practical farmer. On all such questions there is a certain weight that attaches to the opinion of the man of practice as compared with the man of study. On the other hand, all improvements of all kinds have been improvements *on* practice, and have met with more or less opposition, not because they were not improvements, but because they were new. We therefore content ourselves on the present occasion with bringing the subject under the attention of those chiefly interested. But where, we may ask, is the apparatus for artificial drying of the corn, of which we heard so much a year or two ago? Speaking from memory, the inventor wrote to us to say that he had spent all that he could spend in promoting a great national object; that his success was assured, so far as proving the possibility of effecting that object was concerned, but that his heart was nearly broken by the want of interest which the public displayed. If ever there was an occasion on which mechanical harvesting needed to be supplemented by mechanical drying or ripening, it has been in the present season. Not till the very time of harvest did the rain fall. That, when the golden crops had so far matured, their promise should be frustrated by rain, is, in our opinion, a reproach and a scandal to our boasted civilisation. There are times when no human effort could make up for the inclemency of nature. But to lose the harvest, or any considerable proportion of the harvest, of 1881, is to incur a preventible evil,—that is to say, an evil which, whether prevented or not, could have been and ought to have been prevented by the application of known methods. A few hours of drying wind give some small comfort as we write. But again we ask,—Where are the inventions that promise to save and to dry the corn crop?

As the above was written, a notice in the columns of the *Morning Post*, calling attention to the hay-dryer, the invention of Mr. W. A. Gibbs, caught our eyes. By the process, the writer states, wheat, when seemingly worthless, can be restored to wholesome food, almost equal to malt for fattening. A report is quoted from the agent of the Duke of Northumberland as to the effect of the machine in drying hay, which seems to be its original object. The report states that colour and aroma are preserved, and that the hay is not scorched. Two tons an hour is the rate of drying. How far this applies to wheat, and what is the proposed application with regard to the wheat crop, we should be glad to hear. Can Mr. Gibbs give any facts showing the cost and the time that it would take to dry, in the sheaf, a hundred quarters of wheat? That is the way to put the case, as a matter of business.

THE ST. GOTTHARD RAILWAY.

THE SIMPLON AND MONT BLANC TUNNELS.

THE hundred and third report on the progress of the works of the St. Gotthard Railway, reaching to the end of the first half of this year, has just been published, and from it a very interesting picture of the state of this important undertaking may be drawn. The principal and most difficult work, as we are aware, is the tunnel through the St. Gotthard, of a length of 16,304 yards, or nine miles and a quarter. Its adit level has been driven this year, and more; the tunnelling has proceeded for 13,215 yards, and been completed for traffic for 12,174 yards. No fewer than 3,319 workmen are employed in the tunnel, work proceeding uninterruptedly night and day. The contract value of the work done is 2,180,000*l.*, leaving still to be finished work to the value of 85,000*l.* The quantity of compressed air used during the month of June for the rock-boring machines and the locomotives employed in the carriage of materials and *débris* was 5,981,444 cubic feet per day. The temperature in the centre of the tunnel was 29½ degrees C. (85 Fahr.), or 17 degrees more than outside the tunnel. The quantity of dynamite used daily was 567 lb. It may be remarked, in passing, that the temperature in the interior of the tunnel may possibly become lower, as has been the case in the Mont Cenis tunnel, where it has fallen 7 to 8 degrees C. during the last ten years.



On the feeders of the St. Gotthard tunnel, of a total length of ninety-nine miles, and including the lines Immensee-Göschenen, Airolo-Biasca, Cadenazza-Pino, Giubiasco-Lugano, of the calculated 170,486,224 cubic feet of earth and rock, 91 per cent. had been removed or levelled; of the 10,085,512 cubic feet of brickwork and masonry, 83 per cent. had been executed by the end of June. Of the roadways of the fifty-one tunnels, of a total length of fourteen and a half miles, 89 per cent. had been completed. The fact that of the permanent way only 13 per cent. had been laid down has its explanation in the still numerous obstacles. But the above data show unmistakably that the great work is rapidly approaching completion. Within a very short space of time—it may be another year—

Germany will reap the fruits of the energetic efforts made by the representatives of the then North German Confederation at the Bern Conference in the autumn of 1869. The financial sacrifices made by Germany appear trifling compared with the advantages to be gained.

In the meantime, France is preparing to meet the threatening competition by substantial subventions towards the Simplon Railway. If the Mont Blanc project, born of and advocated for locally patriotic reasons,—according to which the northern entrance of the inevitable great Alpine tunnel would lie in French territory, instead of, as in the case of the Simplon tunnel, on Swiss soil,—had not come between as a disturbing factor, the Simplon Railway would, at this moment, have passed the introductory stages of construction. On the north side a completed railway reaches to the foot of the Simplon, at Brieg, in the Rhone valley, which at Lausanne and Geneva joins on to the great North Alpine railway network. On the south, the continuation of the Upper Italian Railway as far as Domo d' Ossola has been secured. There remains, therefore, only the mountain portion (10½ miles long, and estimated at 675,000*l.*) on the granite slopes of the Diveria, from Domo d' Ossola to the southern entrance of the Simplon tunnel at Iselle. The latter will be 11½ miles long, consequently exceed that of the St. Gotthard by 2½ miles, and has been estimated, including the cost for the northern approach and an international terminus at Brieg, at 2,320,000*l.* Of this sum, France is expected to contribute from 1,750,000*l.* to 2,000,000*l.* The Simplon line possesses the advantage, compared with the St. Gotthard and Mont Cenis Railways, of a lower altitude (its level is from 1,312 ft. to 1,640 ft. lower), as well as very convenient junctions. The route from Milan to Paris, compared with the two other lines, will, by the Simplon line, be shortened by 95 miles and 79½ miles respectively. These are reasons enough to justify the conclusion that the construction of the Simplon Railway will follow close upon that of the St. Gotthard Railway. Germany, however, has a start of at least ten years, and there appears to be every probability that she will make good use of her opportunity.

THE GATE OF THE LIONS.

SIR,—I noticed in your leading article (p. 257, *ante*) a reference to the mouldings of the capital between the lions at Mycenæ. I send to you, herewith, a sketch of them made by me a few months since.

I was at Mycenæ many years ago, but did not take any sketches, as I believed that my dear friend, Professor Donaldson, had given them in connexion with the other drawings of the gate which were published by him.

But, very singularly, these mouldings were omitted; and although I have lately consulted, for a special purpose, all the drawings which I could find of Mycenæ, I could find no section whatever of the mouldings.

To draw them with absolute correctness could be managed only from a ladder. My drawing was made from the top of the stone nearest to the carved block, and was verified by a companion who climbed up on the stone with me. I ought to add that I was then quite unconscious of the resemblance of the capital to the Ionic base, and it was not until I happened to look at the sketch its reversed way that I saw the singular resemblance.

So far as I know, it is the earliest specimen in existence, and if, as I strongly suspect, it is actually a copy of a base reversed, it is the very earliest, by very many centuries, known.

Next to it would come the bases shown in the Assyrian bas-reliefs.

In the little museum in which Dr. Schliemann (praise to him!) has preserved many remnants of the old work at Mycenæ, is a portion of a base to a semi-column (*vide* rough sketch), which I at once recognised as being of the same type as the one which Professor Donaldson has drawn at the entrance of the tomb, and which has long been lost.

Mr. Murray pointed out to me lately, at the British Museum, a small part of another of these bases.

A most interesting tomb of the same type as those at Mycenæ and Orchomenos has recently been discovered at Menidi, near Athens.

The Germans have published a plan and description; but, so far as I am aware, nothing beyond this has been made public.

It is very little known, and had it not been for the kindness of Mr. Murray I should have missed seeing it, as the local guides altogether ignore it.

Several details of it, such as the Egyptian method of attempting to relieve the lintel from the weight of the enormous mass above it, are peculiar and well worthy of attention; and, altogether, it would be difficult to find a more interesting vestige of the ancient races, existing, as it does, almost perfect within an easy walk of the Acropolis. T. HAYTER LEWIS.

TECHNICAL SOCIETIES IN HOLLAND.

ACCORDING to an article in one of our foreign contemporaries, there are only two technical societies of importance in Holland,—those for the development of engineering and architecture.

The "Koninklyk Institut van Ingenieurs" (Royal Institute of Engineers) was originally founded at Delft, but since 1860 has been domiciled at the Hague. A special branch has since 1851 been occupied with matters connected with the Dutch possessions in the East.

The Institute holds five regular meetings during the year, one of which is for the purpose of approving the annual report and electing officers. One of the meetings is usually held at some point other than the Hague, and is in connexion with the examination of some work of interest at the town selected. The society receives an annual grant from the State of about 70*l.*, and its property (including its library) was in the last report estimated at a value of about 1,000*l.* The membership of this society is regarded, it is said, as a mark of honour.

The career of the "Maatschappy tot Bevordering der Bouwkunst" (Society for the Development of Architecture) does not seem to have been in the past equally successful with that of the Institute previously referred to. Since its re-organisation last year it seems, however, to have taken a fresh start. Archæological researches come within its sphere of action. Its head-quarters are in Amsterdam, where it has its own premises. Meetings do not seem a strong point with this body, as only one general meeting annually and one excursion assembly are provided for by the statutes. Provision is, however, made for prize competitions of various kinds among the members.

THE INFLUENCE OF BAROMETRIC PRESSURE ON THE DISCHARGE OF WATER FROM SPRINGS.

THIS was the subject of a paper read before the British Association (Section C, Geology) by Mr. Baldwin Latham, M. Inst. C.E. He said that it was alleged, by some of the long-established millers on the chalk streams, that they were able to foretell the appearance of rainfall from a sensible increase in the volume of water flowing down the stream before the period of rainfall. He had, therefore, undertaken a series of observations to investigate the phenomena, and he found, in setting up gauges in the Bourne flow in the Caterham Valley, near Croydon, in the spring of this year (1881), and selecting periods when there was no rain to vitiate the results, that whenever there was a rapid fall in the barometer, there was a corresponding increase in the volume of water flowing, and with a rise of the barometer there was a diminution in the flow. The gaugings of deep wells also confirmed these observations; for where there was a large amount of water held by capillarity in the strata above the water-line at that period of the year when the wells became sensitive and the flow from the strata was sluggish, a fall in the barometer coincided with a rise in the water-line, and under conditions of high barometric pressure the water-line was lowered. Percolating gauges also gave similar evidence, for, after percolation had ceased and the filter was apparently dry, a rapid fall of the barometer occurring, a small quantity of water passed from the percolating gauges. The conclusion arrived at was that atmospheric pressure exercises a marked influence upon the escape of water from springs.

Professor J. Prestwich, who regarded the question as an exceedingly interesting and complicated one, took exception to some of the remarks of Mr. Latham as to the water zones. That gentleman, he said, had treated the subject in a very ingenious manner, but he (the speaker) did not feel they had sufficient evidence before them to determine the question, and he hoped that Mr. Latham would continue his inquiry, and that more importance would be attached to it.

Dr. J. Evans, F.R.S., who had given the subject much consideration, and had taken observations for some years, complimented the reader of the paper, who, he thought, had brought forward facts sufficient to establish his interesting theories. He gave an account of the results which had come under his own observation, and hoped that Mr. Latham would pursue his investigations, and endeavour to ascertain the amount of percolation in the chalk, and the quantity of water available from it for drinking and various other purposes.

Mr. Bateman, C.E., added his testimony to the remarks which had been made respecting the influence of barometric pressure, and spoke of the effects of rainfall upon the water-beds. He gave instances of the influences of the rainfall in different parts of England, and, in conclusion, said they were much indebted to Mr. Latham for his remarks, for they were the result of absolute observations, and might have an actual bearing in all cases where spring water is relied upon for the supply of towns. The observations were also of value as they were the record of facts which might be used in future for scientific purposes.

Mr. W. Topley stated that although they were indebted to Mr. Latham for his valuable paper, the subject was not a new one, it having been brought forward years ago by Mr. Bailey Denton, who had made interesting observations on the subject.

Professor Hughes asked the author of the paper whether he had taken into consideration the hygrometric conditions, as it appeared that he had observed that different flows coincided with the south-west and east winds. The difference in pressure on surface and subterranean waters due to evaporation of surface water under the dry east wind or moist south-west wind, would be so great that it should not be neglected in considering such small differences of actual pressure as are to be referred to the atmosphere.

Mr. J. Lucas, as a resident in the neighbourhood, Mr. Milne, and Mr. Scott, from the Meteorological Office, continued the discussion, the latter observing that Mr. Latham had distinctly proved his case in the paper he had read.

The Chairman (Professor Ramsey) said he had

listened to the paper with great interest. He had given the subject his careful consideration, and the result had been that he had been enabled to predict the state of the weather with tolerable accuracy.

Mr. Latham, in replying to what had been said, stated that, with regard to the remarks of Professor Hughes, he had considered the bearing of hygrometric influences. He had been led to make his observations a good deal as a sanitarian, on account of the knowledge that the town of Croydon was subject every few years to diseases, and which he believed arose from the water supply. There was no doubt that underground water had a wonderful bearing upon the public health of this country, and he hoped that in future more consideration would be given to the connexion of wells with health, for this would be found of great value in relation to the sanitary condition of the country.

ELECTRICITY AND POWER.

SIR WILLIAM ARMSTRONG, in his address to the British Association, as president of the section of Mechanical Science, inquired into the advantages that might be obtained over the steam-engine by resorting to electrical methods of obtaining power.

With regard to this important question, most people, he said, especially those who are least competent to judge, look to electricity as the coming panacea for all mechanical deficiency, and certainly the astonishing progress of electricity as applied to telegraphy and to those marvellous instruments of recent invention which the British Post-office claims to include in its monopoly of the electric telegraph, as well as the wonderful advance which electricity has made as an illuminating agent, does tend to impress us with faith in its future greatness in the realm of motive power as well. The difference between heat and electricity in their modes of mechanical action is very wide. Heat acts by expansion of volume, which we know to be a necessarily wasteful principle, while electricity operates by attraction and repulsion, and thus produces motion in a manner which is subject to no greater loss of effect than attends the motive action of gravity, as exemplified in the ponderable application of falling water in hydraulic machines. If, then, we could produce electricity with the same facility and economy as heat, the gain would be enormous; but this, as yet, at least, we cannot do. At present by far the cheapest method of generating electricity is by the dynamic process. Instead of beginning with electricity to produce power, we begin with power to produce electricity. As a secondary motor, an electric engine may, and assuredly will, play an important part in future applications of power; but our present inquiry relates to a primary and not a secondary employment of electricity. Thus we are brought to the question, From what source, other than mechanical action, can we hope to obtain a supply of electricity sufficiently cheap and abundant to enable it to take the place of heat as a motive energy? It is commonly said that we know so little of the nature of electricity that it is impossible to set bounds to the means of obtaining it; but ignorance is at least as liable to mislead in the direction of exaggerated expectation as in that of incredulity. It may be freely admitted that the nature of electricity is much less understood than that of heat; but we know that the two are very nearly allied. The doctrine that heat consists of internal motion of molecules may be accepted with almost absolute certainty of its truth. The old idea of heat being a separate entity is no longer held, except by those who prefer the fallacious evidence of their senses to the demonstrations of science. So, also, the idea of electricity having a separate existence from tangible matter must be discarded; and we are justified in concluding that it is merely a strained or tensional condition of the molecules of matter. Although electricity is more prone to pass into heat than heat into electricity, yet we know that they are mutually convertible. In short, I need scarcely remind you that, according to that magnificent generalisation of modern times, so pregnant with great consequences, and for which we are indebted to many illustrious investigators, we now know that heat, electricity, and mechanical action are all equivalent and transposable forms of energy, of which motion is the essence. To take a cursory view of our available sources of energy, we have firstly the direct heating power of the sun's rays, which as yet we have not succeeded in applying to motive purposes. Secondly, we have water-power, wind-power, and tidal-power, all depending upon influences lying outside of our planet. And, thirdly, we have chemical attraction or affinity. Beyond these there is nothing worth naming. Of the radiant heat of the sun I shall have to speak hereafter, and bearing in mind that we are in search of electricity as a cause and not an effect of motive-power, we may pass over the dynamical agencies comprised under the second head, and direct our attention to chemical affinity as the sole remaining source of energy available for our purpose. At present we derive motive-power from chemical attraction through the medium of heat only, and the question is, can we with advantage draw upon the same source through the medium of electricity? The process by which we obtain our supply of heat from the exercise of affinity is that of combustion, in which the substances used consist, on the one hand, of those we call fuel, of which coal is the most important, and on the other, of oxygen, which we derive from the atmosphere. The oxygen has an immense advantage over every other available substance in being omnipresent and costless. The only money value involved is that of the fuel, and in using coal we employ the cheapest oxidisable substance to be found in nature. Moreover, the weight of coal used in the combination is only about one-third the weight of oxygen, so that we only pay upon one-fourth of the whole material consumed. Thus, we have conditions of the most favourable description for the production of energy, in the form of heat, and if we could only use the affinities of the same substances with equal facility to evolve electric energy instead of heat energy there would be nothing more to desire; but as yet there is no appearance of our being able to do this. According to our present practice, we consume zinc, instead of coal, in the voltaic production of electricity, and not only is zinc thirty or forty times dearer than coal, but it requires to be used in about six-fold larger quantity in order to develop an equal amount of energy. Some people are bold enough to say that, with our present imperfect knowledge of electricity, we have no right to condemn all plentiful substances other than coal as impracticable substitutes for metallic zinc, but it is manifest that we cannot get energy from affinity where affinity has already been satisfied. The numerous bodies which constitute the mass of our globe, and which we call earths, are bodies in this inert condition. They have already, by the union of the two elements composing them, evolved the energy due to combination, and that energy has ages ago been dissipated in space in the form of heat, never again to be available to us. As well might we try to make fire with ashes as to use such bodies over again as sources of either heat or electricity. To make them fit for our purpose we should first have to annul their state of combination, and this would require the expenditure of more energy upon them than we could derive from their recombination. Water, being oxydised hydrogen, must be placed in the same category as the earths. In short, the only abundant substances in nature possessing strong unsatisfied affinities are those of organic origin, and in the absence of coal, which is the accumulated product of a past vegetation, our supply of such substances would be insignificant. This being the case, until a means be found of making the combination of coal with oxygen directly available for the development of electric energy, as it now is of heat energy, there seems to be no probability of our obtaining electricity from chemical action at such a cost as to supplant heat as a motive agent. Sir W. Armstrong then discussed the transmutation of heat economically into the more available form of electricity, and continued,—It is only the want of an efficient apparatus for converting heat into electricity that prevents our using the direct heating action of the sun's rays for motive power. In our climate, it is true, we shall never be able to depend upon sunshine for power, nor need we repine on that account so long as we have the preserved sunbeams which we possess in the condensed and portable form of coal, but in regions more favoured with sun and less provided with coal the case would be different. The actual power of the sun's rays is enormous, being computed to be equal to melting a crust of ice 103 ft. over the whole earth in a year. Within the tropics it would be a great deal more, but a large deduction would everywhere have to be made for absorption of heat by the atmosphere. Taking all things into account, however, we shall not be far from the truth in assuming the solar heat in that part of the world to be capable of melting annually, at the surface of the ground, a layer of ice 85 ft. thick. Now let us see what this means in mechanical effect. To melt 1 lb. of ice requires 142·4 English units of heat, which, multiplied by 772, gives us 109,932 foot-pounds as the mechanical equivalent of the heat consumed in melting a pound of ice. Hence we find that the solar heat operating upon an area of one acre in the tropics, and competent to melt a layer of ice 85 ft. thick in a year, would, if fully utilised, exert the amazing power of 4,000 horses acting for nearly nine hours every day. In dealing with the sun's energy we could afford to be wasteful. Waste of coal means waste of money and premature exhaustion of coal-beds. But the sun's heat is poured upon the earth in endless profusion,—endless, at all events, in a practical sense,—for whatever anxiety we may feel as to the duration of coal, we need have none as to the duration of the sun. We have, therefore, only to consider whether we can divert to our use so much of the sun's motive energy as will repay the cost of the necessary apparatus, and whenever such an apparatus is forthcoming we may expect to bring into subjection a very considerable proportion of the 4,000 invisible horses which Science tells us are to be found within every acre of tropical ground. But whatever may be the future of electricity as a prime mover, either in a dominant or subordinate relation to heat, it is certain to be largely used for mechanical purposes in a secondary capacity; that is to say, as the offspring instead of the parent of motive power. The most distinctive characteristic of electricity is that which we express by the word "current," and this gives it great value in cases where power is required in a transmissible form. The term may be objected to as implying a motion of translation analogous to the flow of a liquid through a pipe, whereas the passage of electricity through a conductor must be regarded as a wave-like action communicated from particle to particle. In the case of a fluid current through a pipe, the resistance to the flow increases as the square of the velocity, while in the case of an electric current the resistance through a given conductor is a constant proportion of the energy transmitted. So far, therefore, as resistance is concerned, electricity has a great advantage over water for the transmission of power. The cost of the conductor will, however, be a grave consideration where the length is great, because its section must be increased in proportion to the length to keep the resistance the same. It must also be large enough in section to prevent heating, which not only represents loss, but impairs conductivity. To work advantageously on the system a high electro-motive force must be used, and this will involve loss by imperfect insulation, increasing in amount with the length of the line. For these reasons there will be a limit to the distance to which electricity may be profitably conveyed; but within that limit there will be wide scope for its employment transmissively. Whenever the time arrives for utilising the power of great waterfalls, the transmission of power by electricity will become a system of vast importance. Even now, small streams of water, inconveniently situated for direct application, may, by the adoption of this principle, be brought into useful operation. For locomotive purposes, also, we find the dynamo-electric principle to be available, as instanced in the interesting example presented in Siemens's electric railway, which has already attained that degre of success which generally foreshadows an important future. It forms a combined fixed engine and locomotive system of traction, the fixed engine being the generator of the power and the electric engine representing the locomotive. Steam-power may both be transmitted and distributed by the intervention of electricity; but it will labour under great disadvantage when thus applied, until a thoroughly reflective electric accumulator be provided, capable of giving out electric energy with almost unlimited rapidity. How far the secondary battery of M. Faure will fulfil the necessary conditions remains to be seen, and it is to be hoped that the discussions which may be expected to take place at this meeting of the British Association will enable a just estimate of its capabilities to be formed. The introduction of the Faure battery is, at any rate, a very important step in electrical progress.

It will enable motors of small power, whatever their nature may be, to accomplish by uninterrupted action the effect of much larger machines acting for short periods, and by this means the value of very small streams of water will be greatly enhanced. This will be especially the case where the power of the stream is required for electric lighting, which, in summer, when the springs are low, will only be required during the brief hours of darkness; while, in winter, the longer nights will be met by a more abundant supply of water. Even the fitful power of wind, now so little used, will probably acquire new life when aided by a system which will not only collect but equalise the variable and uncertain power exerted by the air. It would greatly add to the utility of the Faure battery if its weight and size could be considerably reduced, for in that case it might be applicable to many purposes of locomotion. We may easily conceive its becoming available in a lighter form for all sorts of carriages on common roads, thereby saving to a vast extent the labour of horses. Even the nobler animal that strides a bicycle, or the one of fainter courage that prefers the safer seat of a tricycle, may ere long be spared the labour of propulsion, and the time may not be distant when an electric horse, far more amenable to discipline than the living one, may be added to the bounteous gifts which science has bestowed on civilised man.

THE SERPENT MOUNDS OF THE SCOTTISH BORDER.

THIS subject was treated of by Dr. Phené in a paper at the recent meeting of the British Association in York. After adverting to the persistent retention of curious customs, and the handing down from generation to generation the traditionary lore of ages long past, the author of the paper referred to some of those which were corroborated by ancient monuments of an unusual kind still famous on the Scottish border. These consisted of sculptured stones, earthworks, and actual ceremonies.

Quoting from former writers, from family pedigrees, and other documents, it was shown that the estates to which such strange matters as follow pertained had been held alternately by those claiming under the respective nationalities, or more local powers, and which, from their natural defensive features, must have been places of Border importance earlier than history records. The district is occupied by the descendants,—often still traceable,—of Danes, Jutes, Frisians, Picts, Scots, Angles, and Normans; and by a comparison of several of the languages of these people, as well ancient as now existing, and also of the Gothic, it was shown in relation to a particular class of the most curious monuments, that the Norse "ormr," Anglo-Saxon "vyrm," old German "wurm," Gothic "vaúrms," pronounced like our word worm; and the word "lint" or "lind," also German, and the Norse "linni," are all equivalent, and mean "serpent"; and in some cases the two words are united, as in modern German "lindwurm," and the Danish and Swedish "lindorm." On this, apparently, rested the names of some of the places having these strange traditions, as Linton or serpent-town, Wormiston or worm's (ormr's) town, Lindisfarne, the Farne serpent island, now Holy Island, &c., and also the various worm hills, or serpent mounds of those localities. It was curious that the contest (like that of St. George) was sometimes with two dragons, as shown on a sculptured stone in Linton Church, and on a similar stone at Lyngby in Denmark, in the churchyard, where there was a tradition that two dragons had their haunt near the church. From these and other facts, the author concluded that the contests were international, and in the case of two dragons, an allied foe, either national, religious, or both, was overcome. He showed from the Scottish seals that Scotland used the dragon as an emblem, apparently deriving it from the Picts; that the Scandinavians also used it; and that these nationalities were antagonistic to the Saxon. In the time of David I. of Scotland, the first great centralisation of Saxon power took place, and the powerful family of the Cumyns took apparently by conquest, at least two of the localities having these strange traditions. And as the political object was to suppress the Celtic and Scandinavian, or other local national feeling, there could be little doubt that, however they obtained them, the persons dispossessed were of one or other of the Northern tribes. Hence, probably, the Middle-age tradition of the slaying of the serpent or dragon, or the serpent or dragon bearer, on the Anglo-Scottish border. But he considered such traditions would hardly have originated through such conquests had not previous marvellous stories existed of the prowess and conquest by the dragon (bearers) of the lands they invaded, all the wonders of which would be transferred to the conqueror's conqueror. Hence these stories were not to be set aside with a sneer, as in them was a germ of history, giving us, perhaps, the only insight we could obtain of the prehistoric customs and mythology of some of the ancient tribes of Britain. Earthen mounds, tumuli, standing stones, &c., still existed in some of these localities, with all of which the dragon serpent or worm was associated in the legends.

The author then described his personal experiences in the still-existing dragon ceremonies in the south of France and Spain, which were always either on the present national or former less important provincial frontiers, and which still formed the subjects of great ecclesiastical ceremonies. These have been already referred to in our pages.

One of the high ecclesiastical dignitaries of the north of England—the Bishop of Durham—is in the position of having to take part in such a ceremony. Whenever a bishop of that diocese enters the manor of Sockburn for the first time, the Lord of the Manor, who holds under the see of Durham, subject to the following tenure, has to present the bishop, "*in the middle of the River Tees*, if the river is fordable, with the falchion wherewith the champion Conyers destroyed the *worm, dragon,* or *fiery flying serpent*, which destroyed man, woman, and child" in that district, and an ancient altar called "*Greystone*," still marks where the dragon was buried.

The subject was illustrated with views of all the places referred to on the Anglo-Scottish, French, and Spanish border counties.

ANCIENT DWELLINGS ON THE YORKSHIRE WOLDS.

To the Anthropological Department of the British Association meeting in York, Mr. J. R. Mortimer contributed an account of the discovery of six ancient dwellings found under and near the British barrows on the Yorkshire Wolds. Dwelling No. 1 was situated at the eastern end of the barrow, which was one of the long type. Its depth from the base of the mound was 6 ft. 6 in., with a floor surface of 9 ft. 6 in. by 7 ft. 6 in., and it was entered by two winding passages 24 ft. in length, the northern one being cut by the side trench of the barrow, showing in this case that the construction of the dwelling had preceded the excavation of the trench, and was therefore older than the barrow. In the material filling the dwelling and its passages were many streaks of burnt wood, a human femur, portions of an urn, and many animal bones, all probably the residue of feasting. A little distance from the dwelling were portions of three more dish-shaped urns, and traces of interments. Dwelling No. 2 contained similar remains, and in Nos. 3 and 4 were found bones of the red deer and the urus. No. 5 consisted of an inner and outer circle of upright posts. In the centre was an oval grave cut 4 ft. into the rock, and containing the flexed human remains of a large male. In front of his face lay a crushed food vase, and close to his left shoulder was a perforated axe hammer. Clayey matter covered the grave and extended to the outer circle of the post-holes. This was believed to be the residue of the sides of the dwelling, in the centre of which its owner was interred, and afterwards the walls were pushed down over the grave and covered with a mound. Mr. Mortimer suggested that the space between the two circles of uprights might have been used for storing heads of grain and other provisions for winter use at a time when man's dwelling was the only building he possessed for all purposes. No. 6 resembles No. 5. Small branches of oak, ash, maple, and other trees, thought to be the remains of the wattled sides of the hut, had left their impressions in the circular bed of clayey matter, some of which showed cuts made with the axe an the saw, seemingly of metal. The droppings from the eaves of this hut had stained the ground all round with colouring from the thatch of the roof, which probably was the straw of wheat, for Mr. Mortimer possessed carbonised grains of this cereal from the primary interment of an undoubted British barrow near. Until the previous dwelling, the occupier had not been interred within the walls of this circle, but just a few feet outside, towards the rising sun. It was accompanied by a delicately-formed flint-knife, lying close to the right arm, and a finely-ornamented food-vase near the head. As in the previous case, the dwelling had been crushed down at the time of interment, and carefully covered with the barrow, showing but a step between the habitation of the living and the house of the dead.

A VIKING'S SHIP.

IN the Department of Anthropology, York meeting of the British Association, Mr. J. Harris Stone read a paper on the Viking ship discovered at Sandefjord, Norway, in 1880. Instead of an antiquated, rudely-constructed, and roughly-finished vessel, with primitively-drawn lines, it was a smart, trim-looking craft, built on what a sailor would call beautiful lines, and was admirably adapted as well for speed as for general seaworthiness. It was difficult to conceive of such a fresh-looking and well-preserved ship being, as it was undoubtedly, about a thousand years old. He feared that the discovery of this ancient galley had not given them any argument in favour of the theory of the growing superiority of mankind in all branches of knowledge and industry. There were no means of knowing whether this ship was or was not concerned in the raid of the Vikings and their followers on our coasts. They plagued Scotland with varying success until 1014, when a treaty was made between Malcom and King Swene, of Denmark, the result of the plucky and steady resistance of the Scotch. The name of the Viking owner of this ship was not known. All that could be said was that he lived at some time during the period from the end of the eighth to the middle of the eleventh century, and that when he died he was buried in his vessel, which was drawn up on land, and had a mound of earth thrown over it, which, luckily for posterity, consisted of blue clay. The vessel which Frithiof beautifully apostrophised, and which entered so largely into the Saga associated with his name, was doubtless a galley similar in all respects to this one. The vessel was now at Christiania. It was excavated at Gdestad, Sandefjord, about half a mile from the present seashore. In this ship the sepulchral chamber in which the Viking's body had been deposited was situated amidships. It was tent-like in shape, made of logs placed side by side, leaning and meeting on a ridge, the side running parallel with the main axis of the ship. The mound appeared to have been entered, no doubt for the purpose of plunder, for none of the Viking's weapons were found, and only a few of his bones were discovered. There were found in the sepulchral chamber the bones and feathers of a peacock, the bones of a little dog, some fish-hooks, and several mountings to belts and harness. Round about the ship were discovered the bones of some nine or ten horses and dogs, which had been sacrificed at the time of burial. The vessel was 77 ft. 11 in. in length between the rabbets at the gunwale, and at the widest part 16 ft. or 17 ft. across. From the top of the keel to the gunwale amidships she was 5 ft. 9 in. deep. She would draw probably not 4 ft. of water, and she had twenty ribs. She was clinker-built, and her planks slightly overlapped, like slates on the roof a house. Her lines were calculated for swiftness as well as for seaworthiness. The planks and timber of the frame were fastened together with withes of tree-roots. The bent timbers seemed to be naturally grown, and not artificially bent. The boards of the sides were of good, sound, well-seasoned, and selected oak, about 1¼ in. in thickness. They were smoothly planed, and firmly riveted together by iron rivets, which had been carefully clinched on either side. There were also a few oaken bolts near the upper part of the sides. He could find no trace of a saw having been used anywhere about the vessel. The planks had their edges moulded. The mouldings consisted of indented lines running down the length of the planks near the lower margins. Bow and stern were of similar shape. They were painted, and must have risen a considerable distance out of the water. The top of each was broken, so that it could not

now be determined whether she originally carried a figure-head or not. The keel was deep, and made of thick oak beams. He could not see whether any metal keel had been fastened to the bottom. In the Frithiof Saga, however, "the ball of copper" was spoken of, and he presumed that there might have been something similar in this vessel. An iron anchor found with the vessel had so rusted away that it could not be preserved. There was no deck to the galley, and the absence of seats for the rowers was notable. The flooring could be lifted to allow of baling out water. The oars were 20 ft. long, and the oar holes, sixteen on each side, had slits towards the stern of the vessel to allow the blade to pass through from the inside. The most interesting thing about the ship was the rudder, which was on the starboard side, a foot or two from the stern. Starboard was a corruption of the word "sturboard," which no doubt owed its origin to the ancient position of the rudder, as in this galley. This rudder resembled a large oar, consisting chiefly of blade and a short handle. It was fixed not to the side of the boat directly, but to the distal end of a piece of conical wood, which projected about a foot from the vessel. This piece of wood was bored down its length, and no doubt a rope passing through it secured the rudder to the ship's side. The steering was effected by a tiller fixed in a hole at the upper end of the handle portion, and probably also by a rope fastened at the lower end of the blade. It was hoped that the correct shape of this galley, which was photographed, would rapidly circulate among artists, and for ever put an end to the curious drawings and paintings of the Viking galleys. The vessel had one mast. In the mound were also found parts of three small oaken boats, generally like a galley itself, a large well-made sheet copper caldron, a few bedsteads like those used in Norway in the present day, some drinking-cups and tubs, and some pieces of carved and painted wood, the use of which is uncertain. Several large round shields of thin wood were also found. These could not have been for defence, but must have been for ornament. A landing-stage made of oak was also found in the mound. The surface of this plank is carved ornamentally, to prevent slipping, and many on seeing the photographs and diagrams would turn their thoughts to the Bayeux tapestry in Normandy, in which were numerous representations of galleys similar to the one now described. The discovery of this galley throws a flood of quite unexpected light upon a period of history which is, perhaps, as dark and obscure as any during historic times.

CHEAP GAS FOR GAS-MOTORS.

MR. J. EMERSON DOWSON, C.E., read a paper on the economical effect of using cheap gas for gas-motors, &c., before the Mechanical Science section of the British Association. In it he described an apparatus invented by him for producing cheap gas, and gave some notes on the economical effect of using such gas with gas-motors, &c. Having reviewed what had already been done to produce a cheap heating gas, the writer stated that he had devised an apparatus which was small in size and easy to work. The apparatus was described in detail. The quantity of water required was very small, being only about seven pints for each 1,000 cubic feet of gas, and except on the first occasion when the apparatus was started, the coil was heated by some of the gas drawn from the holder. For boiler and furnace work the gas could be used direct from the generator; but where uniformity of pressure was essential,—as for gas-engines, gas-burners, &c.,—the gas should pass into a holder. The nature of the fuel required depended upon the purpose for which the gas was used. The cost of making the gas depended to a great extent on the size of the generator; but for three sizes made, the total cost of production for 1,000 cubic feet was 4¼d., 3¼d., and 2¾d., respectively, after allowing 1s. to 1s. 6d. per day for wages. Experiments with the Dowson gas with the Otto gas-engine had proved that one-horse power (indicated) per hour was obtained with a consumption of gas derived from 1·46 lb. of coal, after allowing 10 per cent. for impurities and waste of the latter. Thus, by using the writer's gas a small gas-engine could compete favourably in fuel consumption with the largest and best steam-engines, and a very important saving could be effected when compared with steam-engines of moderate size and of the usual type. The paper concluded with a few words as to other purposes for which the author's gas could be used, and as to its calorific power for heating generally.

Sir F. Bramwell said he was glad to see any method put forward for using the energy in coal. The Otto gas-engine was exceedingly useful, and could be worked with economy. Unless some great improvement could be made in the steam-engine, that was the way in which they would in the future use their fuel. Again, they would not have boiler-explosions. Gas explosions were comparatively rare; but boiler explosions occurred from time to time, and caused about eighty deaths per annum.

SUBSIDENCES IN LAND.

IN the Geological Section of the British Association, a paper on "The Subsidences above the Permian Limestone between Hartlepool and Ripon," by A. G. Cameron, of the Geological Survey of England and Wales, was read by Mr. Topley. In this paper attention was drawn to the numerous forms of shrinkages of the land-surface, often extending to considerable depths into the rocks beneath, observable over the top of the Permian rocks betwixt Hartlepool and Ripon. As a general explanation of their origin, it was suggested that where the underground water, flowing over the limestone surface, reached the margin of the sandstone, it received a check, whereby it accumulated, forming a chain of dams or pools along the line of junction of these rocks. As denudation proceeds, hollows form above, until ultimately the phenomena of the pits appear. This being so, "the water bubbling and frothing all over" was explained without calling in the aid of river-action. Allusion was made to the Home Farm Colliery accident at Hamilton, N.B., in February, 1877, through a subsidence in the gravelly alluvium of the Clyde; also to the recent subsidences at Blackheath, near London; and to the extensive caverns in the hematite districts of Furness.

Mr. W. Whitaker referred to the subsidence at the Blackheath Pit, to which allusion was made in the paper, and expressed his opinion that it was due to artificial rather than natural causes.

Professor E. Hull, F.R.S., stated that great anxiety prevailed in the neighbourhood of Ripon in consequence of the subsidences which had taken place, and he said he should like to know from Mr. Cameron or any one else whether there was a possibility of a large hole being formed under the beautiful cathedral at Ripon, to the destruction of the towers or some part of that edifice.

The Rev. W. H. Oxley, of Grewelthorpe Vicarage, who had witnessed one of these subsidences, which he explained was from 80 ft. to 100 ft. deep, and 200 ft. in diameter, said that he did not think there was any fear, humanly speaking, of any danger occurring to Ripon Cathedral from the cause alluded to.

THE DEVELOPMENT OF THE COLOUR SENSE.

IN Section D, Biology, of the British Association meeting, Dr. Montagu Lubbock read a paper on "The Development of the Colour Sense," in the course of which he said that authors had generally considered the point at issue to be this,—"Is there sufficient evidence to show that the power of perceiving colour has been acquired by man within historical times?" He would extend the question further, and ask, "Is there evidence to show that the power of perceiving colour has been gradually acquired at any time, not only by man in historic or pre-historic times, but by the animal kingdom at large?" He proceeded to treat the question by dividing it into four parts, considering first of all in what the "colour sense" or "perception of colour" consists. He then briefly recalled what had been written on the subject, and the arguments which had been brought forward to prove that the power of appreciating colours had been gradually developed. Having commented on these arguments and considered their value as to the point at issue, he stated the conclusion which must be arrived at on the question. He said reasons more or less conclusive had been given for believing that, as far as man was concerned, no such gradual development could be shown to have taken place. To what conclusion must we come as to such development occurring in the animals of past ages? They had seen that the power of appreciating colour would become more and more perfect in those animals which lived upon coloured food; the same statement, however, might be made with respect to the power of distinguishing form, and there was no evidence to show that the improvement took place in one direction earlier than in the other. Neither did any proof exist that colour perception has been handed down with gradually increasing perfection from one species to another of the animal kingdom. If everything had reached its present form, its present condition, by evolution, colour perception must have done the same, but as yet there was no evidence to show how and through what stages this evolution took place.

Professor Foster having expressed his concurrence with the views of Dr. Lubbock,

Sir John Lubbock, in his comments on the paper, expressed the opinion that the conclusion to which Dr. Lubbock had come was fully warranted by the facts.

A LITERARY BRICKLAYER OF THE SEVENTEENTH CENTURY.

A FEW years ago we gave in the *Builder* some brief notes of a book on building matters, written by one Venterus Mandey. We were unable at the time to furnish any particulars of the author, who was a builder's workman, or bricklayer, as were his father and grandfather before him. We find that Mandey was buried in Ivor Church, Bucks, and his epitaph is given in Le Neve's "Monumenta Anglicana," 1719, which furnishes a brief epitome of his life, and shows that he died in 1701. The epitaph is worthy of reproduction in its entirety, and runs thus:—

"Beneath this place lyes interred the Body of VENTERUS MANDEY, of the Parish of St. Giles in the Fields, in the County of Middlesex, Bricklayer, Son of Michael Mandey, Bricklayer, and Grandson to Venterus Mandey, of this Parish, Bricklayer, who had y^e honour of being Bricklayer to the Hon^ble. Society of Lincoln's Inn, from the year of our Lord 1667 to the day of his death. He was Studious in Mathematics, and wrote and Published three Books for Public good, one Entituled 'Mellificum Mansionis; or, the Marrow of Measuring;' another of 'Mechanic Powers; or, the Mystery of Nature and Art unvayled;' a third, 'An Universal Mathematical Synopsis.' He also translated into English, 'Directorium Generale Uranometricum,' and 'Trigonometra Plana et Spherica, Linearis et Logarithmica,' 'Auctore Fr. Bonaventura Cavalerio Mediolanensi,' and some other Tracts which he designed to have Printed if Death had not prevented him. He dyed the 26th day of July, Anno Domini 1701. Aged 56 years and upwards. He also gave Five Pounds to the Poor of this Parish."

Mandey's "Mellificium Mensionis; or, the Marrow of Measuring," appears to have been first published in the reign of Charles II. In it "a new and ready way is shown how to measure glazing, painting, plastering, masonry, joyners', carpenters', and bricklayers' works," &c. A third edition, with additions (which appears to be a reproduced third edition), issued several years after the author's death, is before us. There is a frontispiece characteristic of the period, representing the author with flowing locks, and a necktie expanding into a tuft of folds upon his breast, with this inscription underneath, "Vera Effigies Venterа Mandey, Etatis Suæ 37 Anno 1682." The volume before us includes "A Garden of Geometrical Roses," &c., and "Some Principles and Problems in Geometry," &c., both originally written in Latin by Thomas Hobbes, but "done into English by Ven. Mandey." The Appendix contains a tract by the author on the "Measuring of Chimneys Reformed." Mandey mentions elsewhere in his book, when treating of glaziers' work, that for those who desired to measure in the decimal way, "I refer them to a Treatise put forth by my friend, Tho. Hammond, *A New and Exact Way of Mensuration*, which I writ for him when I was Apprentice." It will be seen from this that our "seventeenth-century bricklayer" imbibed a literary taste early in life.

To illustrate the method of measuring bricklayers' work in his time, and to assist young practitioners in making an estimate from a given design, Mandey furnishes a ground-plan of a building (no cellars or other rooms being beneath). This seventeenth-century plan is not unworthy of passing notice. There is a frontage of 25 ft. and a depth of 40 ft. The front and rear walls are 2½ bricks thick, and the two rooms, one front and one back, are each lighted by two windows, 4 ft. wide and 6 ft. 6 in. high. The flank walls are 2 bricks thick, and the story 11 ft. 6 in. to the top of the next floor. The door cases in front and rear are 4 ft. wide, and 9 ft. in height. The chimneys stand back to back, and flanking their sides; the stairs

start at right angles to, and nearly midway in, the passage that runs directly from the front to the back door. The enclosure of the stairs, as well as the partitions of the front and back rooms next the passage, are of timber, or intended as such, the style of the period being framed wainscoting and panelled work. Mandey shows young bricklayers how to set out brick arches, circular and elliptical, and to get out their "sommering moulds," and there is no question, considering him in the light of his time, he was a clever, clear-headed, and practical workman. The following, among others, will illustrate the orthography of some building terms in the seventeenth century, as we find them in Mandey's book:—"Plat" for plan, "rear" for rear, "jaums" or "jaumbs" for jambs, "sommering" for sammering, "plaistering" for plastering, "facio" for fascia, "lintol" for lintel, "tarsel" for tassel, "hipt" for hipped, "molding" for moulding, "quines" for quoins, "eves" for eaves, "hanse" for haunch, "center" for centre, &c. Some of the seventeenth-century terms are the proper ones, but the orthography of ordinary words, as well as technical ones, has undergone strange changes in a century, not to speak of those indicated above as belonging to an earlier period. Notwithstanding the advance of technical education, there are not many bricklayers at the present time in the British Islands (leaving literary acquirements aside) who understand their craft as well as it was understood and practised by Venterus Mandey.

BUILDING NOTES FROM THE WEST OF ENGLAND.

The general depression in trade has been, in the past year or two, severely felt by the building trade in the West of England, and business, though perhaps not so bad as it was a short time ago, is not what those engaged in it could wish it to be. House-building, especially of the speculative character, is, compared with what it was five or six years since, at a standstill, and such a large number of houses in all districts are void, that there does not seem a prospect of a speedy revival in this department. In some of the large and poor parishes of Bristol nearly 10 per cent. of the houses are uninhabited; but, rather singularly, though rents have been reduced, owners, unless suffering from special pecuniary pressure, do not seem willing to lower their selling prices. Amongst the more important works in Bristol and the West, which are now in hand or have just been completed, may be mentioned the following:—

The addition of a wing to the Bristol General Post-office is the principal feature in a series of new arrangements which are being carried out for the more convenient transaction of the business in the various departments. The old accommodation has long been found insufficient, and in the alteration not only has the present need been considered, but provision has been made for the parcel-post system, which is to come into operation in a couple of months. The wing has been erected by Messrs. Stephens & Bastow. The ground-floor is used for money-order, savings-bank, life assurance, and annuity business; and the upper portion, which is connected with the main building, is made into a letter-carriers' room. The new building is neat and appropriate in design, and its erection will greatly facilitate the growing work of the office.

Extensive baths and washhouses are to be erected at Jacob's Wells by the Corporation of Bristol. The designs have been prepared by Mr. Josiah Thomas, the city surveyor, and arrangements have been made in them for forty-eight baths,—viz, thirty-six for males and twelve for females,—and for fifty-two washing compartments. All conveniences in the way of machinery for washing, drying, ironing, &c., have been provided. The swimming-bath will be 80 ft. by 49 ft. The total cost has been estimated at 20,000*l*. Application for tenders having been made to twenty-eight of the leading contractors in London and the West of England, that of Mr. A. Krauss, of Bristol, for 15,107*l*., has been accepted. For the mechanical engineer's work tenders have also been received, and that of Messrs. W. J. Fraser & Co., for 3,535*l*. is accepted. In addition to these contract prices 1,117*l*. has been expended in building the retaining wall. The site cost nearly 4,000*l*., so that the work altogether will be an expensive one.

The Bristol Town Council has been ordered by an arbitrator, to whom the matter was referred, to pay 9,639*l*. to the London and South-Western Bank for a piece of ground given up by them (the Bank) in Corn-street and Small-street. The site of the new bank was obtained by pulling down St. Werburgh's Church, afterwards erected in a growing suburb, the tower of which projected on the pavement of Corn and Small streets. The Banking Company, having bought the site, claimed 13,000*l*. for the bit of ground they were compelled to give up. The new bank, a handsome structure as originally designed, is marred by being unfinished on the Small-street side, the stoppage of work being in consequence of a complaint that the lighting of the adjoining commercial rooms would be interfered with if the plans were carried out in their entirety.

The Bristol School Board has just decided upon building another Board school, and have authorised the purchase of half an acre of land for 1,000*l*. near Newfoundland-road, one of the poorer districts of Bristol. The school will accommodate 300 boys, 300 girls, and 200 infants.

An effort having been made to raise the south-west tower of Bristol Cathedral to the same level as the north-western, so as to give due effect to the new western porch, subscriptions were forwarded to the dean, and the work has now been commenced by the contractors, Messrs. Booth.

Messrs. Jones & Co. and Messrs. Baker & Co., two of the large Bristol drapery and fancy goods firms, have materially improved the appearance of Wine-street by additions to their premises. The former's new building is by far the more imposing of the two, and its external architectural arrangements are agreeable. Messrs. Fripp & Saunders supplied the designs.

As a kind of set off against the recent electric lighting experiments, which by the way resulted in nothing as far as permanent use is concerned, the Bristol Gas Company are trying at their own cost Sugg's burners over a mile and a half of roadway leading from the railway station to the Victoria Rooms. Kitt's drum-like reflecting arrangement has been used for some time on part of this route, but pedestrians and drivers pronounce it unsatisfactory.

The Parish Church of Mathern, a village near Chepstow, is being restored. Mathern is remarkable as the burial-place of Theodrick or Teudrick, the hermit king of Glamorgan, who, it is stated, having resigned his kingdom to his son Maurice, led an eremetical life amongst the rocks of Dydyrn. He was, however, dragged from his hermitage to command an army against the invading Saxons, under Ceolwulph, king of Wessex, in the year 600, in the belief that, having always conquered his enemies, he would again. He was victorious, but was slain in the conflict in the Vale of Tintern. A plain mural tablet in the chancel of the present church gives particulars of his death. The estimated cost of the restoration of this interesting church is 2,500*l*.

The Gloucester tramways have been transferred to a new company, the promoters of which are the same as those interested in the Bristol and Bath systems. Important alterations and additions have been made, the expenditure being about 16,000*l*.; the sum, however, represents an actual expenditure during the last two years of 32,000*l*. Mr. A. Krauss, of Bristol, was the contractor for the alterations.

A new Board school has been opened at Newport by the School Board of that town.

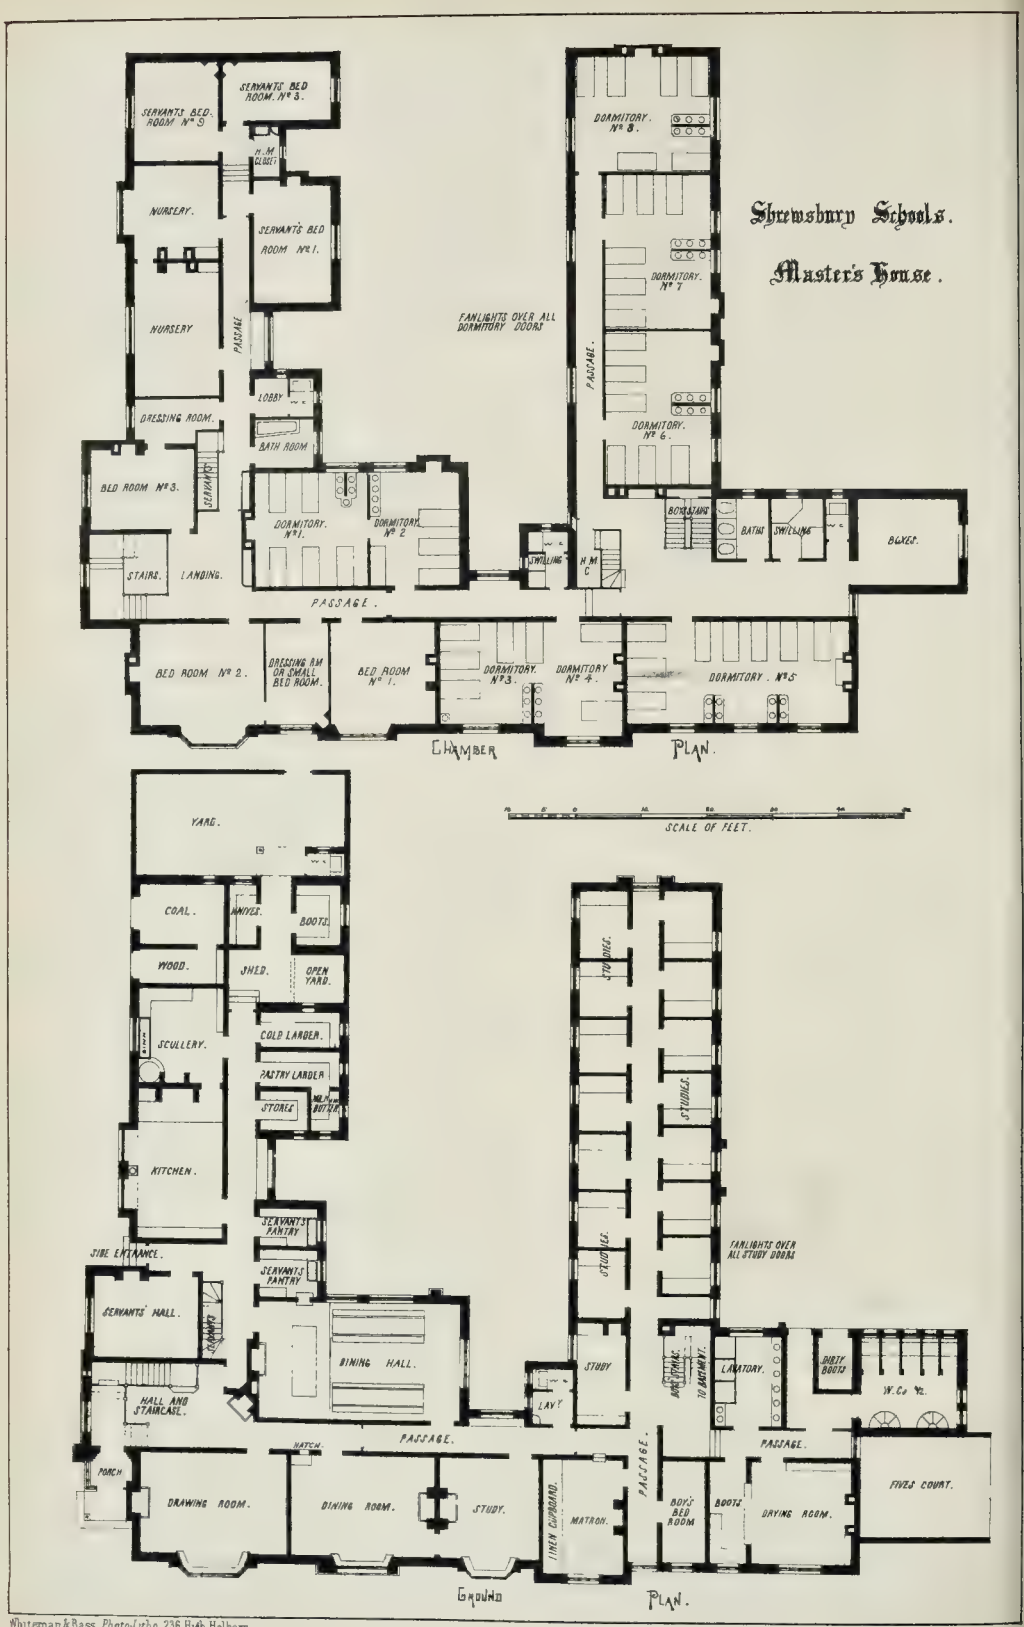
Steps are being taken to provide a winter garden for Weston-super-Mare. The estimated cost is 5,000*l*.

A new chapel is in course of erection in the Claremont District, Bath, for the Primitive Methodist denomination, the memorial stone having been laid by Lady Hayter. The dimensions will be 39 ft. by 43 ft., with five class-rooms beneath. At the rear will be a school-room, 18 ft. by 36 ft. Accommodation will be afforded in the chapel for 250 worshippers. The design is simple, and Mr. Bladwell has been given the contract for 1,100*l*.

The work of building a new church, to be dedicated to St. John the Evangelist, has been commenced at Charfield, the old church, having a history of 600 years, proving inconvenient and insufficient for the changing condition of the neighbourhood. The new building will be in the Early English style, and will be of local stone with freestone dressings. The roof is to be covered with Broseley tiles, and the bell-turret, in the absence of a tower, will be roofed with oak shingle. The length of the building will be 78 ft. in the clear, and the width 29 ft. There will be a vestry on the south-east side, and an organ-chamber on the south side. The porch will be at the north end. The floors will be wood, the aisles of plain tiles, and the pews of oak. The roof woodwork will be pitch pine, and the pulpit will be of oak on a stone base. It is intended to use the old churchyard as a cemetery and the church as a mortuary chapel. The new building is planned to seat 260 persons, and the cost is expected to be 2,500*l*. Mr. William W. Bethell, of Westminster, is the architect, and Messrs. Cox & Gyde, of Stroud, are the builders.

A new church,—St. Andrew's,—has just been completed at Rowbarton, near Taunton. It consists of nave with clearstory, north and south aisles, chancel, vestry, south porch, and tower. The latter is placed at the east end of the south aisle, and the lower stage of it is open to the church. The style of architecture is that of the Early Decorated period. The walls are of West Leigh stone in random courses, lined internally with brickwork, and the dressings are of Doulting stone. The whole of the interior is of brick. The piers supporting the arcades are made of bricks specially manufactured at Chudleigh-road; the other bricks are of Bridgewater manufacture, red and yellow ones and black tiles being arranged in patterns. The roofs are open timbered, plastered between the rafters, and covered with plain tiles of two colours. The plastering is relieved by stencilled ornamentation applied when the mortar was wet. The seating will be of pitch pine, and will be for nearly 500 persons. The chancel and passages are paved with Minton's tiles; the reredos is also of tiles manufactured by Messrs. Craven, Dunnill, & Co. The chancel windows and those of the clearstory have painted glass, by Hardman. The pulpit and font are of Beer stone. No carving or ornamentation has been introduced into the building, but it is ecclesiastical in character. The tower is surmounted by a timber-framed spire, with pale green Westmoreland slates, and rises to a height of 100 ft.; it is capped with a gilded weathercock. The cost of building is about 3,000*l*. Mr. J. H. Spencer, of Taunton, was the architect, and Mr. H. J. Spiller the contractor.

FROM ABROAD.



The harbour works at Stade, which were commenced eighteen months ago, are now approaching completion, and include a quay wall 700 ft. in length. Two cranes, each able to lift two tons and a half, have been erected, and a third, of three times this strength, is being put up. In order to make the harbour of a suitable depth for the tonnage it is meant to accommodate, a steam dredger has for some time been in operation.

The correspondent at Sofia of the *Kölnische Zeitung* calls attention to the position which German architects have recently acquired in that city, and to the steadily increasing demand for glass, cast-iron work, marble work, wire, &c., of German manufacture, in place of the Austrian and English goods which used to have almost a complete control of the market. The new building for the Russian consulate has been built, he says, by a German contractor under a German architect, and from German materials to a large extent.

The German press has been calling attention to the compressed paper for railway carriage wheels, made by Messrs. Adt, of Farbach, which, as to the various qualities requisite for the purpose, is supposed to be superior to wood. On account of its non-conducting properties, it is said to be of special value for electric railways, and for tram-car wheels its suitability is said to be great.

The garrison church at Metz (lately completed) has been in course of erection since the 18th of August, 1875, when the foundation-stone was laid. The total cost has been about 1,250,000 marks, or over 60,000*l*. The German papers speak highly of the work.

A Sanitary Protection Association for Portsmouth, which is intended to undertake the supervision of the drainage arrangements of private houses, so as to ensure their proper sanitary condition, was started at a meeting held on the 5th inst., under the chairmanship of the ex-mayor, Mr. Alderman Cudlipp.

SHREWSBURY SCHOOLS: MASTER'S HOUSE.—Mr. William White, F.S.A., Architect.

Wyman & Sons, Printers 74 Queen St

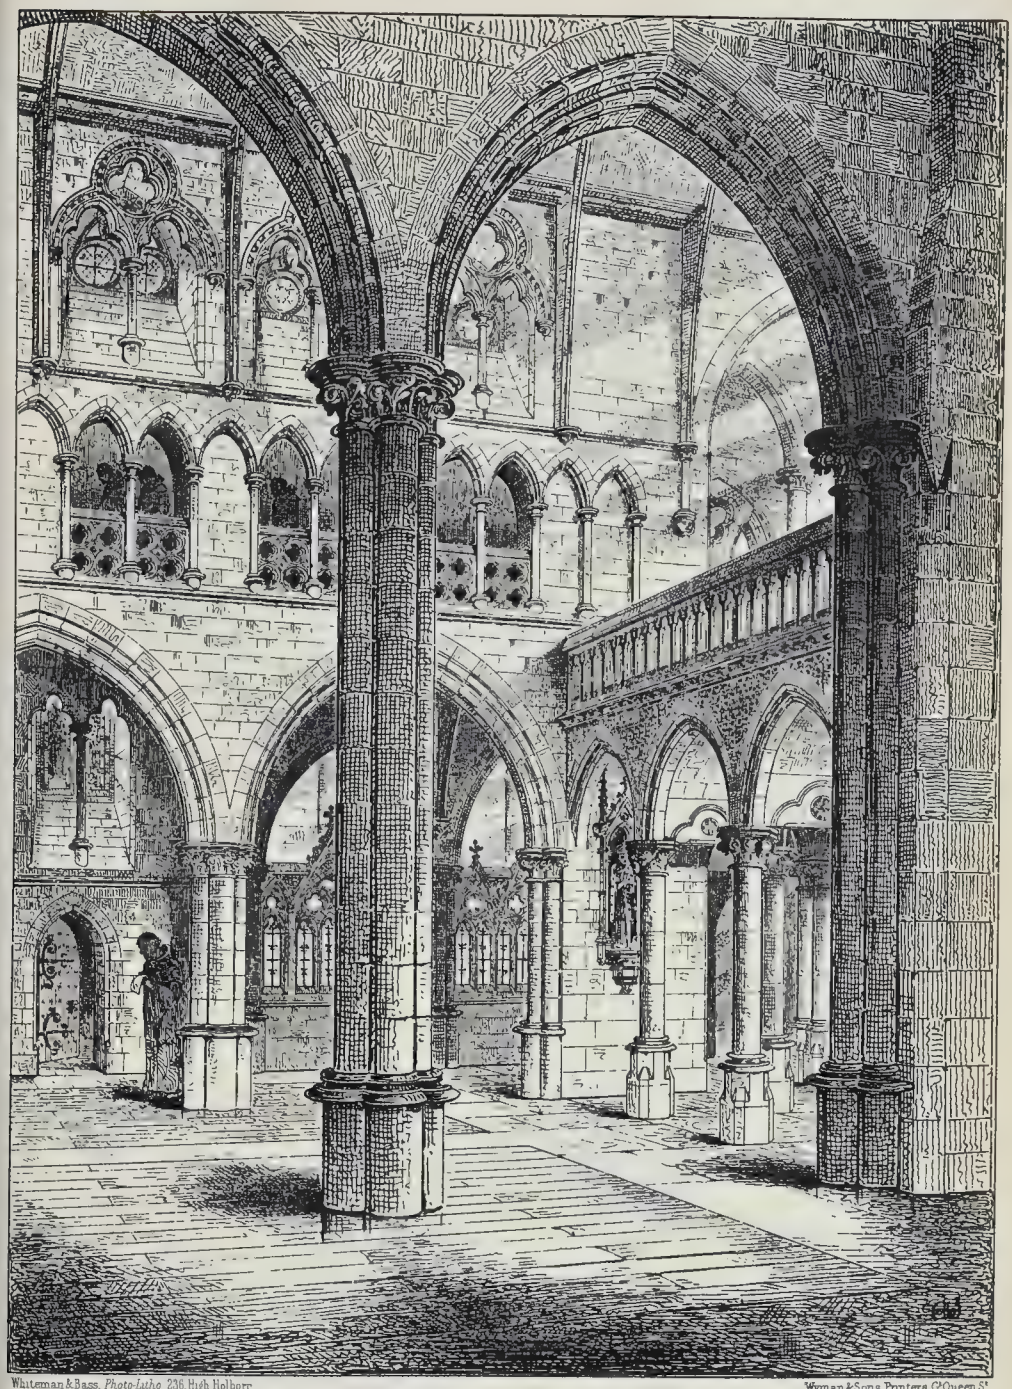
THE NATIONAL THEATRE, PRAGUE.

MEDIÆVAL STREET ARCHITECTURE: HOUSE IN BRUGES.

End of Fifteenth Century or Beginning of the Sixteenth.

SHREWSBURY SCHOOL: MASTER'S RESIDENCE.

THE Shrewsbury School has been removed from its old site across the river to Kingsland. The destination of its old picturesque and characteristic buildings is not yet known. It is now to occupy the large building formerly erected as a charitable institution, and subsequently used as the Union Workhouse. The headmaster's house has been built in the "Queen Anne" style by Mr. Blomfield, and those for two assistant masters by Mr. William White. One of these is given in our illustration. It is built of local red brick, with quoins and moulded arches and other dressings of pressed red bricks. It is covered with plain tiles of brindled tint. It will be seen from the plan that the boys' and the domestic portions are in two distinct wings, with the dining-hall between. The studios are arranged each to take three boys. The studies and dormitories are to be warmed by a circulating system of heated air, combined with the constant provision of pure air.



HOUSE IN BRUGES.

THE sketch we give of an old house at Bruges is an elegant example of the domestic architecture of the Low Countries. The date is not clearly ascertainable, but it may be presumed to be a work of the latter end of the fifteenth century, or possibly of the first few years of that which followed. The insertion of the windows into long sunk panels is a favourite device in Belgium, and is at once a cheap and effective method of giving ornament and light and shade to a large gabled front. It is, of course, one of those things which can easily be overdone, and requires a certain delicacy of treatment to look thoroughly satisfactory.

From a constructive point of view, the porch shown is not above criticism, as the thrust of the cusped arch has nothing to sustain it, and is dependent upon an iron tie to prevent its forcing the column which supports the angle of the building out of perpendicular. The builders, however, had the honesty to show this weakness, and, knowing that an iron tie was necessary, they made it a feature of the design. There are traditions at Bruges that Van Eyck and Memling lived in this house, but we were unable to obtain any reliable information upon the subject.

THE NATIONAL THEATRE, PRAGUE, BOHEMIA.

THIS theatre, which had been ten years in building, and was opened about four months ago, was destroyed by fire in August last. The loss is estimated at about 100,000*l*. Its large size and grandiose effect justified the inhabitants in considering it one of the most important monuments of their city. It was intended that plays in the national idiom of Bohemia, the Czech language, should be performed in it, in order to keep alive the sentiment of nationality and the love of country. It is to be rebuilt forthwith. It was insured for about half its cost, and subscriptions, from high and low, are flowing in to complete the amount required.

THE R.C. CHURCH OF OUR LADY AND ST. DENIS, AT ST. MARYCHURCH, TORQUAY.

MESSRS. JOSEPH A. HANSOM & SON, ARCHITECTS.

GATEWAY TO S^T AUGUSTINE'S ABBEY - BRISTOL.

WEST VIEW.

Whiteman & Bass, *Photo-Litho* 236 High Holborn.

Wyman & Sons Printers

ST. MARYCHURCH, TORQUAY.

VISITORS to Torquay will find pleasure in visiting the now completed R.C. Church of Our Lady and St. Denis, at St. Marychurch, of which the spire is now a prominent land-mark for miles around. In our present number we give an internal view, taken from the north porch looking across the nave and two aisles to the Lady Chapel, which does not occupy the usual place at the east end, but is placed for necessary reasons at the south side of the south aisle, at its western extremity, and measures 30 ft. by 12 ft. To the right of the picture is a large tribune for the orphans under the care of the nuns of the third order of St. Dominic, to whose convent the church is attached. The whole cost of the church, of which a part has been in use some years, has been defrayed by Mr. Chatto. It consists of a chancel, 30 ft. by 20 ft., with nuns' choir on the south side and sacristies and presbytery on the north; nave, 103 ft. 6 in. by 22 ft. 3 in.; north aisle, 88 ft. 6 in. by 12 ft. 6 in.; and south aisle, 103 ft. by 12 ft. 6 in.; the Lady Chapel already alluded to; and the tower and spire at the west end of the north aisle, the baptistery forming the lower part. The internal dimensions are 133 ft. by 47 ft. 3 in. The church is built in local limestone and Chudleigh limestone, with Box-ground and Westwood-ground dressings outside, and Corsham Down inside. The Bath stone was supplied by Messrs. Randell & Saunders. The spire is, however, all built in Portland stone, and terminates in a copper cross, which communicates with and forms part of the lightning conductor, which is a ribbon 4 in. broad by ⅛ in. thick. The top of the cross is 176 ft. above the floor level, which is nearly 300 ft. above the level of the sea. The entasis of the spire is peculiarly graceful, being a rise of 9 in. in 90 ft.

Mr. Eddles, of St. Marychurch, took the contract for the completion of the building at 10,146*l.*, but several additions have been subsequently made. Those concerned had to deplore his loss during the course of the works, and they have since his death been carried on by his sons and executors, Messrs. William & Jesse Eddles. Mr. Condy is the clerk of the works.

The altars and statuary are by Messrs. Farmer & Brindley, Mr. Earp, and Mr. Boulton, most of the foliage being very creditably done by Mr. Jackman, of St. Marychurch. The font was carried out by Mr. Blackler, of St. Marychurch, and is, together with its steps, of polished local limestone in different colours. The whole of the works are from the designs of Messrs. Joseph A. Hansom & Son, architects, of 27, Alfred-place West, South Kensington; and since the retirement of Mr. Hansom, sen., from the firm, the works have been carried on under the superintendence of Mr. Joseph Stanislaus Hansom, F.R.I.B.A. The copper cross on the spire was executed by Messrs. Hart, Son, Peard, & Co., from the designs of the architects.

The church is now in regular use, but no bells are as yet placed in the tower. It is proposed to have carillon chimes.

THE ABBEY GATEWAY, BRISTOL.

THIS remarkably beautiful example of Norman architecture originally formed the entrance to St. Augustine's Abbey, which is now known as Bristol Cathedral. It is in a wonderful state of preservation, the whole of the detail, save such as is within about 2 ft. 6 in. of the ground, being nearly as perfect as on the day when it was placed there. It would appear to have been erected during the reign of Henry II., as a superstructure of the Perpendicular period of architecture, and built at the expense of one Abbot Newland, or Nailheart, bears an inscription, couched in very ecclesiastical Latin, to the effect that King Henry II and Lord Robert Fitzhardinge were conjointly the founders of the monastery. Their statues and arms are to be seen upon Abbot Newland's building, and also those of Edward the Confessor and Richard de Clare, Earl of Pembroke, the latter two bearing title-deeds in their hands, and Lord Berkeley holding a model of the building. Pembroke's arms are also emblazoned at the high altar of the cathedral, together with those of Lord Berkeley and Henry II., and hence it may be inferred that some religious establishment endowed by Edward the Confessor and an Earl of Pembroke existed previously to the erection of Sir Robert Fitzhardinge's magnificent building.

It is impossible, in viewing this archway, to avoid being struck by the careful thought and painstaking consideration which has been bestowed upon each minutest detail by its twelfth-century architect, as well as by the broadly artistic effect which he has imparted to it as a whole; thus, every fillet maintains a uniform width throughout its length, every nailhead is perfectly cut, and some of the ornaments are undercut in a way that must have cost the workman much time as well as rare dexterity. The arrangement of the carved decoration of the four external members of the chief arch evidences much taste and artistic feeling; round the outer member, and in high light, runs a slightly relieved riband ornament, fantastically twined and knotted around two continuous roll mouldings. Within this, and, by contrast, in the deepest shadow of all, is a member studded with bold lozenge ornaments, so deeply undercut as to stand clearly out against the darkness behind. Within this, again, the decoration, though less vigorously rendered, is sufficiently defined to be easily followed by the eye; and the inmost member of all, which is practically only slightly shaded, is chased with a light chain of zigzags. In the caps of the interior arcade, the architect has freely indulged his fancy, scarcely two of them being alike in design.

The view given is made from carefully measured drawings made by myself some years ago, and might be described as a detail perspective view, the jointing of the stones, as well as the position of each ornament, being faithfully rendered.

LOUIS KNAPP.

MICA.

THIS industry is represented at the Breslau Exhibition in the full extent of its different branches, by the collection of Max Raphael. The fire-proof, glassy, and transparent mineral is found in America in large quantities, but not in sufficient abundance to supply the wants of that market, and hence there is a large export of the article from this side of the Atlantic in the leaf form. It is there mostly used for covering the openings in furnaces, so that the chemical changes which are being produced by the heat can be controlled. It is also used for purposes of a domestic nature.

Mica is found in Ural and Finland. The Swiss and Tyrolese Alps produce the most favoured descriptions, which are also worked up in Thuringia into the forms required for commerce. The raw material is in the shape of thick leaf-formed slabs, which can be divided to form almost any degree of thinness, and it is in different shapes and thicknesses that the article is packed for export to America, this being a main feature of the trade. Another use to which it is put is the decoration of pottery.

The immutability of this product, its resistance to heat and damp, the readiness with which it receives impressions of colours, photographs, &c., enable it to be put to a variety of uses.

Herr Raphael does not confine himself to supplying the material, but in many cases sends the article out in its manufactured state. It is used in telephones, and for ventilators it is preferred to metals, as they are liable to oxidation. It is also used for more complicated purposes in lamps, &c., in cases where glass has hitherto been employed.

There is, however, a limit to its applications, and one of our foreign contemporaries remarks that the church-windows, with paintings and shadings, which are exhibited, cannot be considered as producing the effect of painting on glass, although in themselves they are interesting trials.

There is another exhibitor of this article, Jaroslaw, who shows some handsome lamp-shades, which, besides being ornamental in themselves, have the advantage of not curling with heat, as is the case sometimes with shades composed of paper.

St. Paul's, Brixton.—The above church was consecrated on the 29th ult. It is situated in the Ferndale-road. It was built by Mr. Jones, of Gloucester, from the designs of Messrs. Habershon & Fawckner, of Bloomsbury-square. The lighting arrangements were carried out by Messrs. Jones & Willis, of London and Birmingham, and we are informed that the same firm supplied the other interior fittings.

THE BRITISH ARCHÆOLOGICAL ASSOCIATION IN THE WEST OF ENGLAND.

CONCLUDING our record * of the proceedings in connexion with the Malvern Congress of this Association, we have to note that on Saturday, the 27th of August, there was an excursion to the Herefordshire Beacon, Midsummer Hill, Bronsil Castle, and Eastnor Castle. Little Malvern was the first place visited, and here sketchers were charmed by the church-tower. Mr. Daniel Parsons read a paper, stating that it was certain that the church began to exist as far back as 1125. He had examined the original register of the Priory of Worcester. Little Malvern was given by the 27th Bishop of Worcester to the Benedictines, who were the great church-builders in Worcestershire. The Bishop retained jurisdiction over the place. In 1171 two brothers came over to Little Malvern and founded the church. No dedication of the church had taken place up to that date. In 1237 a Provincial Council held in London ordered that all churches built with walls perfect should be consecrated within two years. In the Malvern district the difficulty of getting materials must have been almost insuperable; and to that he attributed the delay in consecration. In 1182 the dedication took place. The Bishop preached in the Chapter-house, and his text was still preserved. In 1480 the discipline of the house had become relaxed. Nash stated that the monks had become people of bad character; but this was not the case. In 1534 the monks were compelled to give up their jurisdiction, and the property was afterwards given by deed to a member of the Russell family. Mr. Parsons described in detail the painted glass of the large window, showing sympathies with the House of York. It was mentioned that the preservation of one of the windows was due to the late Mr. Albert Way. Mr. Parsons also described the tiles, including one which is also found at Great Malvern, with the following inscription:—"Thenke mon thi liffe mai not eu endure: that thow dost thi self of that thow are sure: but that thow kepist un to thi sectur [executor's] cure: and eu hit [it] availe the hit is but aventure." The date of this tile is about 1450. After looking at the church, the excursionists, under Mr. Berington's guidance, visited Little Malvern Court and gardens. A large number went beneath the enormous lime-tree, under which, on one occasion, 183 persons were assembled. The branches trail all around on the ground. This is supposed to have been caused by weights placed on the tree. Mr. Berington stated that the tree was not much more than 150 years old.

From Little Malvern the party proceeded to the Wind's Point, where they left the carriages in order to inspect the two great camps of the Malvern Hills. Like some Dover or Namur of the olden days, the great hill fortress of the Herefordshire Beacon frowns upon the valley below. Its belt of ramparts having been passed, the archæologists at length reached the great central mound, from which, the day being clear, there was a magnificent view of the country for many miles around. Mr. J. Tom Burgess pointed out the various objects of interest in the distance. Mr. Edwin Lees, in a paper which he read on the hill, maintained that the camp was of two ages, and the work of two separate tribes. He attributed the greater part of the camp to an age prior to the Romans. He thought the camp was held by the Welsh, and pointed out that it was not until the days of Athelstan that the Welsh were driven from the Malverns across the Wye. To this latter period belonged the golden coronet which was found at Burstner's Cross. Mr Lees gave an account of the finding of the crown, and quoted Card, Nash, and other writers. He had fought many battles on the hill, and was prepared to hold his own against any theory of Caractacus having been there. Sir J. A. Picton pointed out that there were people in this country before the Celts, and that they naturally occupied the high points for defence. He thought the camp might have been occupied by various peoples at various times.

Mr. J. Tom Burgess maintained that the camp was one of the frontier fortresses of the Silures. On the opposite side of the valley was Bredon Hill. This, from the remains found upon it, was undoubtedly one of the outposts of the Romans in the time of Ostorius, and along the whole line

* See pp. 265, 311, *ante*.

of hills, which stretched from Bredon to the south, every point of vantage once bristled with Roman watchfires. In a direction due east there was another line of earthworks and fortresses, which were the frontier line of the Cornabii. Their remains could be traced along the eastern bank of the Severn; and looking to the north in the far distance was the Wrekin, which was the capital of that tribe. A little farther to the west could be seen a line of fortresses, which might be attributed to the Silures. Far away to the south was the Bristol Channel, which represented the southern end of their territory. The Herefordshire Beacon was about the centre of that line, and the camp was one of the largest fortresses in the country. During the nine years' war which Caractacus waged against the Romans, and, indeed, during the whole of the twenty-five years which elapsed from the landing of the Romans to the period of the subjugation of the people in whose ancient territory they now stood, there must have been conflicts going on in that neighbourhood.

From the Herefordshire Beacon, the archæologists walked across the hills, under Mr. Wilson's guidance, to the Midsummer Hill. Mr. Burgess pointed out that the hill probably took its name from the Midsummer or Beltane fires. It was afterwards suggested by Mr. Piper that the old name of the hill was Bronsil, a name surviving in the castle in the valley below. The ramparts of the camp and the hollows, where formerly there were habitations, were pointed out. At the Holly Bush Pass the excursionists took carriages and drove to Bronsil Castle. Of this fine old castle of the fifteenth century nothing now remains except one of the round towers. The old fragment of stone, the clear, broad waters of the moat, and the tangled vegetation, make up a pretty picture. The castle was a double-moated one. The outer moat, however, now only remains. Mr. G. H. Piper read a short paper on the history of the castle, mentioning that it was built by Richard, son of John, first Lord Beauchamp of Powyke. It was suggested by one of the party that probably the area was moated before the Conquest. Mr. Burgess did not think that moated areas were generally to be traced further back than the time of Stephen.

After a beautiful drive by the side of Eastnor Park, with its almost unrivalled herd of 800 deer, the Somers Arms was reached, where luncheon was partaken of, and the visitors afterwards wended their way to Eastnor Church, where the monuments to various members of the family of Earl Somers were scanned.

From the church it is not a long walk to Eastnor Castle. This was commenced in the earlier part of the century, and is built in the old baronial style. The former castle stood at the west end of the present lake.

At the evening meeting in Malvern, Mr. G. H. Piper read an account of the excavations which were made on the Herefordshire Beacon in September, 1879. In one hut, hollow pottery, and the bones of the horse, sheep, deer, and other animals, were found. These were exhibited on the table. At the same meeting, a paper by the Rev. W. S. Symonds on "The Battle of Tewkesbury" was read by Mr. Wright. As this meeting, strictly speaking, terminated the Congress, votes of thanks were given to the President, Lord Alwyne Compton, and to many other gentlemen, for services rendered in connexion with the week's proceedings.

Extra excursions and meetings took place on Monday, Tuesday, and Wednesday, the 29th, 30th, and 31st of August. On Monday a visit was paid to Worcester, where the members were received in the Guildhall by the Mayor (Alderman Townshend). Alderman Noake gave a short account of the Guildhall, mentioning that Thomas White, a pupil of Sir Christopher Wren, was its architect. He also described the pictures, including that of Sir John Pakington, the fourth baronet of Westwood, and that of George III. by Reynolds. The various charters of the city had been carefully laid out on the tables by Mr. S. Southall. Mr. W. de Gray Birch, F.S.A., said that this was one of the best collections of charters they had seen in their rambles for many years. The first charter was that of King Richard I., written in the beautiful handwriting of that period. In this charter the city of Worcester was called a ville. The burgesses were to pay 20*l.* yearly to the exchequer, and for that they were to do as they pleased within the city. The charter was witnessed by the Archbishop of Canterbury and other nobles, and was dated 1189. The second charter was most important as far as the liberties of the city were concerned. Worcester was here called a *civitas*, and the inhabitants were described as citizens. The charter was dated the 11th year of Henry III., and was witnessed by the Bishop of Bath and other dignitaries. This charter granted various immunities. It gave permission for a merchant guild with hanse; it provided that no one should bring merchandise into the town without permission; and it also granted scot and lot, stallage and tollage; 30*l.* per annum was to be paid to the exchequer. Appended to it was one of the finest specimens of the weaver's art to be found in England. He congratulated the Corporation of Worcester on the excellent way in which the charters of the city had been preserved. Mr. Birch then read a portion of a paper on "The Anglo-Saxon Charters of Worcester Cathedral." The cathedral church of Worcester was, he said, justly celebrated for its Anglo-Saxon literary treasures. Saxon charters were a grand record of our insular history; and to them we must look for nearly all our information respecting real property and many other matters. They were also of value as illustrating the minuter details of early English history. It was the work of the Teutonic races to infuse vigour and sanctity into institutions that were perishing through their own corruption. Roman law looked to the individual member of the State. Teutonic law based itself upon the family bond. It was highly probable that the Saxons had symbolic means of effecting the transfer of land. The Runic characters, in use up to the arrival of Augustine, then gave way to the Roman writing. In the time of Wulstan there were between 200 and 300 Saxon charters in the monastery of Worcester. Wulstan ordered the deeds to be transcribed. Of these nearly one-half were now unknown, except in the form of transcript. There were twenty original Anglo-Saxon charters of Worcester in the British Museum. With the exception of Christ Church, Canterbury, no other cathedral or monastery had contributed so many original Saxon documents to the Museum. Mr. Birch, having given some details as to the Worcester Anglo-Saxon charters, said that the total number of Anglo-Saxon charters preserved was very limited, perhaps not exceeding 2,000. These documents were beginning to show signs of decay, clearly foretelling that the time would come when a Saxon charter would be no longer in existence. What students really required was a *corpus* of these charters. This work, which Kemble almost accomplished, should now be undertaken by a society.

From the Guildhall the visitors walked to the Cathedral, where the Dean gave a short account of the history of the fabric, acknowledging his obligations to the description by Professor Willis. The church built by St. Oswald in the tenth century had entirely disappeared. At the time of the Conquest Wulstan was Bishop of Worcester. An attempt was made to dispossess him, but in the end he was retained. Wulstan determined to rebuild the cathedral church, and began the work in 1084. In 1092 he held a synod in the crypt, which, said he, "I have built from the foundations." The crypt was, therefore, a dated example of Early Norman architecture. In 1203 Wulstan was canonised. In 1216 King John died; and before his death he said he commended himself to God and St Wulstan, the last great English saint. In 1218 the cathedral was solemnly dedicated. That was the Norman cathedral, and probably the building had been going on from the days of Wulstan. The Norman work remaining was interesting as giving the key to the construction of the building. The Norman cathedral was exactly of the same size westwards as the present cathedral, with the pillars in the same places. The apse of the Norman choir was near where the tomb of King John now stood. In 1224 the foundation of the new choir was laid. Between 1317 and 1321 the north aisle of the nave was built by Bishop Cobham. As a whole, the cathedral was completed by the year 1400. The Dean then conducted the party over the cathedral, pointing out the remains of the old Norman building in a blocked-up arch over the marble string-course of the choir, and in the arches of the south choir aisle. Mr. Loftus Brock was of opinion that the latter were part of Wulstan's building, especially from the wide joints; but he thought that the carving was of later date. It was suggested by a member of the Architectural Association, when visiting the cathedral a week or two ago, that the passage to the north of the Chapter-house was a fragment of the Church of St. Oswald, and, therefore, was tenth-century work. Mr. Loftus Brock pronounced against this theory. Mr. Lynam thought the work the earliest in the cathedral, and ante-Norman. In the Chapter-house the Dean mentioned that the round Norman arches were still behind two of the Perpendicular windows. The Dean, in replying to a vote of thanks, mentioned that the total cost of the restoration of the cathedral was 130,000*l.*

On Tuesday the last Worcestershire excursion took place. Leaving Worcester in carriages, the archæologists drove through Whittington to Cruckbarrow Hill. Clambering up the hill-side they soon reached the top, from which, when the weather is fine, there is a beautiful view. Mr. J. Tom Burgess said that Cruckbarrow was one of about twenty hills he knew with this name. This was a marl-stone hill, which appeared to have been escarped as a beacon between the Malvern Hills and a series of earthworks extending along the valley of the Severn. After a long drive past Spetchley and Broughton Hackett, the carriages drew up in front of Huddington Court and church. The church was first inspected. Mr. Loftus Brock said that it was not often that they saw a church in so unaltered a state. Archæologists though they were, they must be grateful to think that, probably through the work of their own society, and other kindred societies, the taste and regard for old churches had been so much developed that there were now few opportunities of seeing churches in such a poor condition as Huddington. The church, however, was interesting as an example of the little village church of the early part of the fourteenth century, in which fewer alterations of a later date had been made than was commonly the case in such buildings. The building was not unworthy of study. It contained the original timber roof, which, if the plaster were taken off, would be seen to great advantage. It was surprising what a different effect would be produced by the outlay of a few hundred pounds. He hoped their visit would result in drawing attention to the church and preserving it. It was apparent that, unless something were done, a catastrophe would occur to its bulging walls and rotten timbers. The church contained a chancel-screen of Jacobean date. The tiles of the floor were of very great beauty, but there were now only about a dozen in anything like a state of preservation. It was seldom they saw a porch of so early a date in such a good state of preservation. He considered it to be as old as the church. The hall was, as in many other cases, near the church. The lord of the manor in the old times was the patron and father of the village, looking after his own comforts in the hall and the spiritual welfare of the people. The ladder was of the same date as the porch.

Mere Hall was next visited. It is one of the finest specimens of the timbered houses for which Worcestershire is famous. Different opinions were expressed as to the date of the building. The house bears the date 1337. Mr. Loftus Brock and Mr. Reynolds thought that the building was erected in the time of Charles I. Other gentlemen thought that it was Elizabethan. Mr. Brock said that it was a matter of considerable gratification to him to stand beneath the roof of that house, not only because it was a specimen of the black and white house so common in the district, but for personal reasons which it was pleasant for him to remember. On the disforesting of that district, it appeared that oak was so abundant that farm-houses and even cottages were erected with it. On the building was the date 1337. His own impression was that the date was placed there for a sort of double purpose. The date of 1637 so nearly fitted in with the style of the house as to justify them in believing that the house was erected at that time. The house was figured in Habershon's "Half-Timbered Houses." He had referred to his personal feeling in being in that house. Under the direction of his late partner's father, Mr. Habershon, the house received certain alterations and additions to adapt it for the purposes of a modern residence. Probably it was to Mr. Habershon that they owed the existence of the house at all. It had been stated that Mr. Habershon covered the new work of the house with black and white stripes, in imitation of the old work. They might depend upon it that the work was originally erected without those stripes, as Mr. Habershon would be the last man to create an architectural sham. It

was a matter of gratification to see that Mr. Bearcroft, the owner, had done so much to uphold and preserve to future generations so interesting a specimen of a style of architecture which was every day disappearing. Apart from the cordial reception Mr. Bearcroft had given them, they owed him a debt of gratitude for the care he had bestowed on the house.

From Mere Hall the party drove to Droitwich, where luncheon was provided at the Raven Hotel,—a building of some archæological interest. At St. Andrew's Church the Rector was in attendance to receive the visitors. The whitewash in this church, though it mars, does not conceal the original beauty of the mouldings and carvings. Mr. J. Tom Burgess said that Droitwich was believed to be the Salinæ of the Itinerary of Richard of Cirencester. There were indications that in ancient times it was a city of considerable importance, arising from its salt springs. A tesselated Roman pavement found at Droitwich was preserved in Worcester Museum.

From Droitwich the archæologists drove to Salwarpe, where Canon Douglas and Mr. J. T. Mence received the party. The nave of the church is late twelfth-century work. One of the most striking points of the excursions has been the immense quantity of work of the Transition period between Norman and Early English that has been seen. The latter half of the twelfth century was evidently a great church-building period in Worcestershire. To the Norman nave of Salwarpe beautiful Decorated aisles have been added. In the chancel, which was rebuilt in 1848, there is a well-preserved recumbent effigy of the beginning of the fifteenth century. The parish chest encloses some curiosities, which were shown by Mr. Douglas. From the church it is only a few yards' walk to the Court House. The present house was probably erected about the time of Henry VII. About that time, or later, the house was granted to the Talbots. Salwarpe Court, like many other fine houses in the district, has its herring-bone brickwork painted white. It is the opinion of some architects that the effect of these old houses would be heightened by leaving the brickwork untouched.

On Wednesday the members of the Association and their friends made the last excursion. They proceeded by an early train to Cheltenham, where the doors of Thirlestaine House were thrown open by the courtesy of the Rev. J. E. A. Fenwick, M.A., and the trustees of the late Sir Thomas Phillipps, bart., and the party were permitted to inspect the valuable library and interesting pictures which used to be so fondly treasured at Middlehill. Some of the choicest MSS. of this vast collection were exhibited in one of the rooms. Mr. E. Maunde Thompson, F.S.A., the keeper of the MSS. in the British Museum, explained, in a brief address, the value and importance of these and other rare works in the library, which were unequalled outside the national collection.

After lunch, which was partaken of at the Plough Hotel, Mr. T. Morgan, F.S.A., hon. treasurer, who presided, moved a vote of thanks to Mr. J. Tom Burgess, F.S.A., for his valuable services during the excursions. We may add that for a portion of our notes of the proceedings of the Congress we are indebted to the columns of the very old-established newspaper known as *Berrow's Worcester Journal*, which, dating back to 1690, is the oldest existing provincial newspaper in the kingdom. Mr. J. Tom Burgess is its editor.

DRAWING IN AMERICA.

WE have received from America the "Annual Report on Industrial Art Education in the State of Massachusetts for the year 1880," and "Plan and Graded Programme on Instruction in Drawing for the Public Schools" in the same State, both by Mr. Walter Smith, State Director of Art Education in Massachusetts. They are valuable and interesting documents, and show the thoroughness with which Mr. Walter Smith is pursuing his work.

The following propositions define the position taken on this question of industrial drawing in the public schools:—

"1. All children who can be taught to read, write, and cipher, can be taught to draw.

2. Drawing, by the law of Massachusetts, is required to be taught to every child as an element of general education, like reading, writing, and arithmetic.

3. As an elementary subject, it should be taught by the regular teachers, and not by special instructors.

4. The true function of drawing in general education is to develop accuracy of perception and to exercise the imagination, thereby tending to produce a love of order and to nourish originality.

5. Educationally, drawing should be regarded as a means for the study of other subjects, such as geography, history, mechanics, design. In general education it is to be considered as an implement, not as an ornament.

6. The practice of drawing is necessary to the possession of taste and skill in industry, and is therefore the common element of education for creating an enjoyment of the beautiful, and for a profitable, practical life.

7. In the primary, grammar, and high schools, drawing is elementary and general; in the normal and evening schools, advanced and special,—for teaching purposes in the first, and for skilled industry in the second.

8. Good industrial art includes the scientific as well as the artistic element; science securing the necessity of true and permanent workmanship, art contributing the quality of attractiveness and beauty. The study of practical art by drawing should therefore comprehend the exactness of science by the use of instruments, as in geometrical drawing and designing, and the acquisition of knowledge of the beautiful, and manual skill in expression, by freehand drawing of historical masterpieces of art and choice natural forms.

9. Drawing may now, therefore, take its legal place in the public schools as an element of, and not as a specialty in, education, at as little cost as any other equally useful branch of instruction, with the prospect that at a future time as many persons will be able to draw well as can read and write well, and as large a proportion be able to design well as to produce a good English composition."

Mr. Walter Smith, who is an Art Master of South Kensington, was an esteemed correspondent of our own before he went to America, and will be remembered by many of our readers. We send to him across the broad Atlantic our heartiest good wishes.

THE FIRE IN CHEAPSIDE.

THE recent fire in Cheapside and Bread-street leaves after its ravages, and for the short time it must remain before the whole corner is demolished, the ruin of a well-constructed modern stone building, a picturesque and novel sight, such as is scarcely to be found nearer to London than the remains of the Tuileries or the Palais du Quai d'Orsay, destroyed by the Communists in 1871. Bread-street, indeed, had a narrow escape, and with it, a neighbourhood fraught with interesting associations; for, as all Londoners know, it was in this street, within a short distance of the fire, that Milton first saw the light (1608), and he was baptised in the Church of Allhallows in the same street. It was from his father's house in Bread-street that Milton made his first removal in that series of changes of residence in London, all of which are well known,—better known, perhaps, than those of any other great Englishman who has migrated from spot to spot. Milton's house in Bread-street,—before the Great Fire of 1666, in which the whole neighbourhood was destroyed,—was, we have contemporary authority, constantly visited by strangers and foreigners.

The antiquarian associations of this street are great, and such associations always possess an interest even in the midst of the excitement of modern existence. In Bread-street it was that stood, in the days of Queen Elizabeth, the Mermaid Tavern, of poetic memory,—the tavern where met Shakspeare and Ben Jonson, Raleigh and Marlowe, and that set of literary contemporaries who adorned so brilliantly our English Renaissance, whose poetry, while it breathes with all the grace and polish of Classic tradition, rings with the healthy British joviality that endeared the hours spent in Bread-street in the memories of the merry band who filled the quaint bar and back room of the oft-sung Mermaid, in the poetry of whose frequenters the literary student welcomes that first expression, as a polished authority has well put it,* of the growing consciousness on the part of English-men of the commercial and constitutional future of this our great country.

It is a further association that may almost be said to belong to Bread-street, that nearly opposite it, in Milk-street, Cheapside, was born the courtly, learned, witty, and unfortunate Sir Thomas More, buried under the quiet shadow of his parish church at Chelsea.

From such recollections of the past the stirring incidents of the present moment are eminently calculated to distract the most concentrated attention. The recent fire in Cheapside, will, we hope, at least afford the benefit of one lesson by which all may profit. The *employés* in Messrs. Copestake's extensive premises, owing to the excellent practice into which they had been drilled by previous rehearsal of the manner in which they were to act in cases of emergency, were able not alone to protect their own property, but to render able assistance to the firemen in their dangerous task. This example is one which should be more largely made known and introduced than is at present the case. In these days of an almost excessive love of athletic exercise, we can imagine no better direction in which an expenditure of young force can be turned than towards such an aim. Our volunteer movement has shown, within only a few weeks, its vigorous vitality. In America every citizen, unless we are much mistaken, is called upon to be either a militiaman or a fireman.

And as we are speaking of America, while, in such an instance as the recent destructive fire in Cheapside, not an imputation can be thrown on the skill of our firemen, it has long been admitted that, across the water, the fire-brigade with its apparatus is more fully organised than here, and that in the case of a building well alight in England little is usually done beyond limiting the spread of the disaster. Should such a state of affairs be allowed to continue? Should not, as one precaution at least, the increased use of the fixed hydrants common in America, running from top to bottom of the huge warehouses, and in which the water-power is ready at any instant on the highest floors, be insisted upon in all new buildings? Must another winter, with its inevitable tale of disasters, pass away without some progress being registered, even in our already well organised and nobly-served Metropolitan Fire Brigade?

As will be inferred from what we have said above, the huge premises of Messrs. Copestake had a narrow escape. Had they got fully alight Bow Church would have been in great jeopardy. The main frontage of Messrs. Copestake's premises is towards Bow-churchyard,—not a wide thoroughfare, what width there is being usually more than half taken up with boxes, bales, straw, and other combustible matter. In fact, it seems to be made a sort of packing-yard. On the south of the church the "churchyard" is continued in the form of a narrow passage running into Bow-lane. In this passage are some large premises occupied, apparently, by a firm of wine merchants or druggists, and it will hardly be credited that this firm seem to be in the habit of stowing a large number of hampers, crates, and boxes, quantities of straw (loose and in trusses), and other highly inflammable matter, to the height of 5 ft. or 6 ft., close against the south wall of the church, under its windows, and even in immediate contact with the very wood of the south door. A fusee or lucifer carelessly thrown down amongst this heap might easily convert it into a large bonfire, and, given a favourable wind and a dearth of water, the Church of St. Mary-le-Bow would soon be "burnt out." The City Church and Churchyard Protection Society might take this matter under its cognisance.

* Mr. A. J. Beresford-Hope, M.P., in his inaugural address at the Archæological Congress held in London, 1866.

SIR,—Passing along Cheapside shortly after the outbreak of this fire, I was much struck with the inability of the fire brigade to prevent the ignition of houses on the opposite side of Bread-street. It occurred to me that if blankets, or other thick woollen material, could be hung out of the upper windows to overlap those below, the engines could easily keep these saturated, and thus prevent the possibility of firing the woodwork thus covered. The roofs should be similarly protected, and evaporation alone would keep the temperature down. Such a simple process would have saved the premises of Messrs Cow Hill, & Co., and all those on that side of Bread-street. It would not merely save them from destruction by fire, but the ruin of the stock by water.

If the demand arose, some coarse felt would be manufactured for the purpose, and suitable lengths form part of the equipment of each engine or hose cart.

That the usual means of arresting the spread of fire should be by reducing neighbouring properties to a mass of wet rubbish speaks volumes for the scientific enlightenment of the age we live in. I forbear to speak of fireproof flooring

THOS. C. SORBY.

THE SEWERAGE OF EASTBOURNE.

IN connexion with the recent Sanitary Exhibition at Eastbourne, a visit was paid by a deputation of the Association of Municipal and Sanitary Engineers and Surveyors to the Sea-Wall works, where a discussion was held, after which they proceeded to the Ejector Works at Seaside, where, after reviewing the works, the following paper was read by Mr. C. Tomes, the Town Surveyor, a discussion following:—

Before describing to you the action of the ejector system as applied at Eastbourne, I propose to briefly state the reason for its adoption. The main sewer of the town is for a distance of about 1,400 yards from the outfall towards the town below high-water level, and in consequence of this, like many other coast towns, it is for some hours during the day tide locked. This causes the sewage to back up and be stagnant in the lower part of the town, there not being sufficient time between high and low water for the whole of it to pass away. It was therefore resolved, upon my report to the Board, to adopt Mr. Isaac Shone's ejector system, which, by the use of compressed air, will maintain a constant flow through the outfall sewer both at high and low water. The arrangement by which this is effected I will now proceed to describe. The air for supplying the ejector is compressed by two 14-in. "compressors" invented by Mr. Thomas Sturgeon. These are worked by a pair of high-pressure expansive and condensing engines (the cylinders of which are 10½ in. in diameter), fitted with the Hon. Charles Parson's patent variable expansion gear and equilibrium piston slide valves, the engines being arranged so that they can be run either separately or together. The steam is supplied from two "Kesterton" boilers, provided by Messrs. Tangye Brothers, of Birmingham. The compressed air is passed to the three ejectors for a distance of about 350 yards through 6-in. cast-iron flange pipes, and at the same time air is being stored in the receivers for use during the night if required, thereby effecting a great saving in night labour, and at the same time keeping the ejectors constantly supplied. A reducing valve is placed at the compressing station to regulate the pressure of air required by the ejectors. A connexion between the air receivers and the governor is also made, which, when the pressure in the receivers rises to a certain height, cuts the steam off from the cylinders of the engines and stops them, opening again and allowing the engines to run when the pressure lowers. Air from this station can be carried to any number of ejectors placed at different parts of the town, and at any distance from the compressing station. To pass on to the actual disposal of the sewage. The main sewer, by means of a penstock, is diverted from the direct outfall to the sea, and conducted to the ejectors, which then proceed to work. These consist of hollow cylindrical vessels, 4 ft. 6 in. in diameter by 5 ft. high, which are placed entirely below the level of the sewer, so that the sewage passes by gravitation into them through an 18-in. inlet-pipe, placed on the town side of the penstock. Inside the ejectors are two small cylinders, each being open at one end. The upper one, which is termed the "bell," is suspended with its open end downwards, and the lower one, termed the "cup," with its open end upwards, so that the latter is always filled with sewage. The "cup" and "bell" are connected by a rod, and a small rod passes from the upper one, the "bell," through a stuffing-box in the cover to a lever which acts upon a small slide valve governing the action of the automatic piston valve, so as to alternately admit compressed air to the ejectors and let it escape. When the ejectors are nearly full, the sewage, as it rises, encounters the "bell," closes up its open end, and compressing the air within it, lifts it up, thereby drawing back a small slide valve, admitting air pressure to one, and exhausting at the other end of the automatic piston valve, the outer ends of which act as the motion piston, the middle portion acting as the valve regulating the inlet and exit of compressed air. The piston-valve being thus moved over, opens the port admitting compressed air to the ejector, which forces the sewage out through a delivery-pipe into the sewer, on the sea or outfall side of the penstock, ball valves being placed both on the inlet and outlet pipes to prevent the back flow of sewage. The "cup" and "bell" arrangement being balanced, and the weight of sewage in the cup being neutral so long as it is submerged, retains its position until the ejector is nearly empty, and the sewage begins to pass below the cup. The dead weight of sewage in the cup then acting downwards pulls the cup and bell down, reversing the small slide valve, and so, shooting the piston-valve over to the opposite side, shuts off the compressed air and opens the ejectors to the exhaust. The compressed air at once rushes out, allowing a fresh charge of sewage to enter the ejectors, and the action is repeated. Valves are placed both on the inlet and outlet pipes of the ejectors, so that they may be readily disconnected and worked separately. In conclusion, it will be seen by this that the action of the ejectors is entirely automatic and depending upon the rate of flow of sewage. In full work each ejector will fill and discharge in one minute; but during the hours of minimum dry-weather flow the ejectors will be much longer in filling, thus doing only as much work as is actually required. The population of Eastbourne is 24,000, and putting the quantity of sewage to be disposed of at 40 gallons per head, the amount of sewage to pass through the outfall sewer will be 960,000 gallons per day. As I have before mentioned, the ejectors are capable of filling and discharging once in each minute, and their combined capacity being 1,500 gallons if the engines run 10 hours per day, they will dispose of 900,000 gallons in the 10 hours, air being stored at the same time in the receivers at six effective atmospheres. The receivers will contain at this pressure 50 charges, each of which will eject 1,500 gallons, making a total of 75,000 gallons which can be disposed of automatically during the night; the average thus disposed of by the ejector during the day and night amounting to 975,000, or 15,000 gallons in excess of the present requirements.

THE WANDSWORTH NEW PUBLIC HALL.

THE new Vestry and Public Hall, which has for some time past been in course of erection in High-street, Wandsworth, is now fast approaching completion, and it is expected that it will be ready for opening in about a month. The building has an elevation to High-street of about 60 ft. in width, and upwards of 50 ft. in height, with a tower at the west end 80 ft. in height to the top of an ornamental cresting. The main face of the elevation is in red brick, with Dumfries stone dressings and ornamentation, in which some elaborate carving is introduced. This more especially applies to the three lofty windows overlooking High-street, from which the public hall, the principal room in the building, is partially lighted. Between and on each side of these windows there are fluted pilasters, having carved capitals. The central window is surmounted by an ornamental pediment, whilst the two windows on each side of it have segment-arched heads. The elevation is surmounted by a gable in Dumfries stone, with vases on either side; behind rises a high-pitched roof. The lower part of the elevation is arched, forming an arcade and covered carriage-way leading to the entrance-hall of the building.

The building internally contains a large number of apartments, adapted for the various purposes to which they are intended to be appropriated. The principal approach to the building leads into an entrance-hall 18 ft. square, on the right hand side of which is the vestry-clerk's private office, an apartment 17 ft. by 19 ft., together with several clerks' offices and committee-rooms adjoining; and in the rear of the building, on the ground-floor, is the board-room for the general meetings of the vestry. This apartment is 31 ft. in length and 19 ft in width, and is at present receiving its fittings. The floors of the entrance-hall and those of the several corridors on the ground-floor are all laid with Minton's encaustic tiles. In the basement of the building is the heating chamber, from which the whole of the building is heated and ventilated, the heating apparatus having been supplied by the Thames Iron Company. Strong-rooms have also been constructed in the basement, from which there is a lift to the public hall and to the upper portions of the building. The public hall on the first floor is approached by a stone staircase 5 ft. in width, having ornamental cast-iron balusters. This apartment, which is the principal room in the building, is 73 ft. in length and 38 ft. in width, exclusive of the stage or platform, which is 12 ft. in depth and 20 ft. in width, the extreme length of the hall being 85 ft., running the entire depth of the building from the High-street frontage to the rear. The hall is lighted by a range of six windows on the east side, in addition to the three windows in the High-street elevation already referred to. It is 25 ft. in height from the floor to the ceiling. The floor of the hall is fireproof, constructed on Fox & Barrett's principle. The hall is being decorated. It has a coved ceiling divided into panels, which are being painted in varied delicate tints, with gold enrichments. A frieze of festoons is carried round the room immediately under the coved ceiling, and the walls are divided into large panels by double pilasters with ornamental gilt capitals. In connexion with the hall, on the west side, there are several ladies' and gentlemen's retiring-rooms and committee-rooms. It is computed that the room, which is intended for public meetings, lectures, concerts, and other entertainments, will have accommodation for about 1,000 persons.

The architect of the building is Mr. G. Patrick, of Drummond-chambers, John-street, Adelphi; and the contractor, Mr. Parsons, of Wandsworth. The cost of the building will be about 9,000*l.*

PATENT RECORD.*

APPLICATIONS FOR LETTERS PATENT.

3,606. C. D. Abel, Southampton-buildings. Metallic structures suitable for barracks, workshops, and other buildings. (Com. by La Société Nouvelle de Construction, Paris.) Aug. 19, 1881.

3,620. J. Craig, Kilmarnock. Dressing enamelled bricks, tiles, or slabs. Aug. 19, 1881.

3,629. C. Drake, Battersea. Baths. Aug. 20, 1881.

3,630. C. Drake, Battersea. Facing bricks. Aug. 20, 1881.

3,633. S. Mead and J. W. Tiptaft, Birmingham. Adjusting action for toilet-glasses, swing-sashes, doors, &c. Aug. 20, 1881.

3,648. W. H. Stephenson, Blackburn. Heating apparatus. Aug. 22, 1881.

3,689. W. H. Windsor, Brentwood. Bolt for fastening doors. Aug. 24, 1881.

3,693. H. C. V. de Ahrbecker, and H. E. J. Hamkens, Lambeth. Fluid meters and ball-cocks. Aug. 24, 1881.

3,707. W. R. Lake, Southampton-buildings. Water-closet apparatus. (Com. by the Hartford Sanitary Plumbing Company, Hartford, U.S.A.) (Comp. spec.) Aug. 25, 1881.

3,708. A. C. MacLeod, Shrewsbury. Floors or surfaces for skating upon. Aug. 25, 1881.

3,713. C. D. Douglas, Glasgow. Baths. Aug. 25, 1881.

NOTICES TO PROCEED

have been given by the following applicants on the dates named.

August 23, 1881.

1,367. T. Wrigley, Chancery-lane. Construction of ceilings. (Com. by S. Müeller, Nürnberg.) March 28, 1881.

1,690. W. G. Sloane & J. Sloane, Dublin. Apparatus for heating and ventilating drying-rooms, &c. April 19, 1881.

1,812. A. E. Carey, Newhaven, and E. Latham, Birkenhead. Manufacture of concrete, &c. April 27, 1881.

1,854. J. M. Day, W. R. Green, & H. C. Walker, Great Dover-street. Construction of lifts and hoists, &c. April 29, 1881.

2,653. W. Barton, Boston. Stoves. June 17, 1881.

3,020. W. Howitt, Ilford. Sash-bar for the roofs, &c., of horticultural buildings, &c. July 9, 1881.

August 26, 1881.

1,817. Mr. W. E. Gedge, Strand. Artificial stone. (Com. by G. Boden, Atlantic City, U.S.A.)

2,276. J. McI. Shaw, Glasgow. Kitchen-ranges. May 24, 1881.

ABRIDGMENTS OF SPECIFICATIONS

Published during the Week ending August 27, 1881.

162. T. Rowan, Ryde. Ventilating buildings.

An air inlet box is provided, having two divisions, one filled with coke, the other with dry charcoal, limestone, &c. The air is made to pass through these, whereby it is purified. From this box a shaft leads the air into the building or room. Just above the end of this air inlet pipe is the mouth of the air ejecting pipe. This pipe is led to above the roof, where it terminates in a cowl, which

* Compiled by Hart & Co., Patent Agents, 28, New Bridge-street, E.C.

produces an induced current of air up this pipe. Jan. 13, 1881. Price 6d.

243. J. Shanks, Bristol. Discharge apparatus for water-closet and similar cisterns.

The cistern is fitted with a syphon discharge-pipe, the short leg of which has a conical mouth. Beneath this is placed a cup, which fits it, which cup is connected to the closed handle. The water in the cistern is a little below the bend of the syphon, but when the cup is raised, the syphon is brought into action. (*Pro. Pro.*) Jan. 21, 1881. Price 2d.

244. J. McAlister, Barrhead. Apparatus for heating water.

A number of tubes are employed which are of a long narrow section, the broad sides being placed vertically, and the water travels backwards and forwards through these in succession, being all the time exposed to the heat. (*Pro. Pro.*) Jan. 20, 1881. Price 2d.

248. E. de Pass, Fleet-street. Apparatus for heating by hot water and steam.

The steam, being raised in the boiler, is led to the room to be heated, and then taken through a surface heater filled with water. This is heated by the partial condensation of the steam, and the condensed water flows back to the boiler through a special system of pipes. The surface heater communicates with the hot-water stove by which the room is warmed, which thus absorbs the heat of the steam, and imparts it to the room. (Com. by E. Körtling, Hanover.) Jan. 20, 1881. Price 6d.

251. G. Whitehead, Heywood. Archimedian ventilators.

This relates to those ventilators which have revolving tops and screws or fans, and has outlet passages between the screw, and the revolving top, to prevent any down-draught. (*Pro. Pro.*) Jan. 20, 1881. Price 2d.

254. L. W. Sutcliffe, Birmingham. Self-feeding and smoke-consuming fires, &c.

As relates to fireplaces, a hopper is constructed at the back of the grate with a sloping bottom, and divided from the fire by upright bars. It has also a divided sliding top. Slack or fine fuel is placed in this, and the top is closed. When the fire is lighted, it communicates its heat to the slack, the gases of which pass through into the front fire, and are thus consumed. Jan. 20, 1881. Price 8d.

261. W. Jones, West Derby. Chimney-pots and exit ventilators.

An outer shaft is fitted round the chimney shaft above the roof, above which it rises about 2 ft., and a double cone is fixed in the centre of the top of the outer shaft, with one apex placed at the mouth of the inner shaft. (*Pro. Pro.*) Jan. 21, 1881. Price 2d.

270. C. D. Abel, Southampton-buildings. Portable heating apparatus.

This is applicable to heating apparatus of the kind described in the specification of Patent No. 382 of 1880. A water vessel is made of the required shape and size. This has a tube through it, in which the fuel is burnt. This fire-tube may be surrounded by an annular air space if required. (Com. by A. Morel, Epinal, France.) Jan. 21, 1881. Price 6d.

287. J. W. Midgley & B. E. Midgley, Keighley. Stoves, &c.

To economise coal the back of the stove is made adjustable and pivoted at the bottom close to the ribs. It can thus be regulated as desired. (*Pro. Pro.*) Jan 22, 1881. Price 2d.

297. M. Lenzberg & M. M. Lenzberg, South-place, Finsbury. Stair-rod eyes.

That part of the eye which is fixed to the stair is made of the usual shape, but the eye proper is made separate and screws into a hole in the fixed part so that in can be be adjusted to any thickness of carpet. Jan. 22, 1881. Price 6d.

305. A. C. Henderson, Southampton-buildings. Gas-stoves.

Under the stove is an undulated or smooth cone in form of a parabola, permitting the reflection of the light and heat of the burning gas. (Com. by MM. André & Legrand, Lyon.) Jan. 24, 1881. Price 6d.

307. J. Rule, Dublin. Apparatus for preventing the freezing of water in water-pipes.

An air-valve is fitted above the supply-pipe of the ball-cock, so that when the ball-cock is in action the valve is closed by the pressure of the water. A tap is fitted to the pipe at as low a level as possible below the cistern, and when this is opened, air is admitted through the air-valve, and the pipe is emptied. Jan. 24, 1881. Price 6d.

311. H. E. Newton, Chancery-lane. Ornamenting various surfaces.

To ornament surfaces of plaster, wood, &c., in imitation of marble, the surface is first washed with an adhesive material. A thick paste is then prepared of carbonate of lime and flour, &c., which is placed on the surface to represent the veinings. When this is dry the colour is added. (Com. by E. A. Batonnier, Vitry le François, France.) Jan. 24, 1881. Price 4d.

315. R. C. Robinson, Preston. Manufacture of roofing-tiles.

The head portion of the tile, and the rib, or projection, are formed before the body of the tile in a die, which has opposite its mouth a hollow stop for the rib. The body is then formed in the usual way. (*Pro. Pro.*) Jan. 24, 1881. Price 2d.

2,303. A. M. Clark, Chancery-lane. Fluid meters.

These have a hinged valve on the induction pipe, which throws the fluid on to the blades of an impact wheel. These blades are less in height than the vertical diameter of the pipe, so that the excess liquid can pass over them. The shaft of the impact wheel passes through the top of the meter, and actuates the counting mechanism. (Com. by B. Holly Lockport, U.S.A.) May 25, 1881. Price 6d.

THE LATE MR. CHAS. GRAY, ARCHITECT.

WE have to announce with regret the decease, on the 1st inst., of Mr. Charles Gray, who was best known many years ago as one of the founders, and, if we mistake not, the first honorary secretary, of the Architectural Association of London. The origin of the society is, in fact, to be found in the form of a letter addressed to this journal by Mr. Gray in 1846, advocating the establishment of some better means of education for young architects, and we are always glad to remember that we supported the enterprise so heartily as we did. Since that time the Architectural Association has done a great work, in connexion with which the deceased gentleman well deserves to be remembered with honour. As an architect in practice, Mr. Gray, in early life, attracted some notice by the erection of several buildings divided into suites of residential or business chambers. They were built almost always on corner sites, and commanded attention by their bold and simple style of treatment in brickwork. They are to be seen chiefly in the neighbourhood of Covent-garden and the Strand;* although others of his works, at South Kensington, of more ornate character, Highgate, and elsewhere, do him equal credit. In the competition for the Memorial Church at Constantinople, a design sent in by him was awarded honourable mention, and he took part in other competitions with a due share of praise, if not of profit. Unfortunately, however, he was led into building speculations, and although he did well at the outset, in the end, as he said, "the lawyers had all his money." Mr. Gray's age, at his death, was fifty-three; and we are sorry to hear he has to be numbered amongst those who have left a family unprovided for.

BOROUGH OF PORTSMOUTH SEWAGE DISPOSAL.

THE Corporation of Portsmouth have issued advertisements offering a premium of 500 guineas for the best scheme to dispose of their sewage, and it is one of the most remarkable productions in the shape of an invitation to intended competitors that we have seen. By its terms, and the wording of the memorandum accompanying the plans, we can hardly believe the Corporation to be in earnest. They tell intending competitors that a plan of the borough, showing the sewers and a memorandum thereon, will be forwarded for the sum of two guineas. What this deviation from the custom means we cannot say, but it is as absurdly ludicrous as it would be if the Corporation advertised for a town clerk or for borough surveyor, and asked intended candidates for a fee for the list of duties.

Are we to understand by this that the corporation of Portsmouth are so extremely poor as to be unable to afford giving the plans and instructions gratuitously? If so, how will they possibly be able to pay the premium? If, on the other hand, they have been led into this stupid blunder from a parsimonious economy, it would be well for intending competitors to ask themselves the question if such parsimony will not prevent their parting with the 500 guineas under any circumstances. As to their memorandum, it is conspicuous for its absence of all that information necessary to the engineer to shape a scheme. ENGINEERS.

THE CARRIAGE WORKS AT NEASDEN.

THE raising of the last principal of the roofs of the Metropolitan New Carriage Works, Neasden, was celebrated by a dinner the other day at the White Hart Hotel, Willesden, the chair being taken by Mr. Jackson Gawith, doctor to the works.

These works are on an extensive scale, comprising carriage repairing and painting shop, 194 ft. by 163 ft., and 36 ft. in height up to the gables. The walls are faced with paviors, supplied by Messrs. Nash, of Slough. The floors are of wood blocks on concrete. The buildings are heated with exhaust steam conveyed through the sheds in 5-in. and 7-in. pipes. There are also stores, 208 ft. by 43 ft.; and saw-mill, 136 ft. by 55 ft. Already 50,000 cubic yards of excavation have been removed. It has taken 10,000 yards of concrete, two million of bricks, 350 tons of iron, 400 squares of roofing, 1,400 tons of lime, supplied by Messrs. Greaves, Bull, & Lakin; the ironwork by the Horsley Iron Company, Tipton. The glass was supplied by Messrs. Hawkes, of Birmingham.

The plans were prepared by the Company's engineer, Mr. J. Tomlinson. The contractor for the work is Mr. J. Garlick, Saltley Works, Birmingham. The clerk of works is Mr. John Winstone; the manager of the works, Mr. Henry Charlton, under whose personal supervision the works were carried out. The total cost was about 30,000*l*. Additional buildings are contemplated.

* A view of one of these, Tavistock Chambers, Southampton-street, Strand, will be found in our volume for 1867, p. 375.

STAINES.

A NEW river-wall is being constructed at the back of the new Town-hall, Staines, in order to obtain a regular frontage-line to the river, together with a convenient landing-stage and steps leading to the new roadway at the side of the Town-hall. It is being built partly with bricks and partly with cement concrete rusticated blocks, and will form a retaining-wall to the vacant land at the side of the river. It will be raised, in order to prevent the land from being swamped by the winter floods. The spare land will, in all probability, be sold for building purposes, in plots suitable for a class of house much needed in the town. The whole of the works are being carried out by Mr. Ralph Fitt, C.E., the surveyor to the Staines Local Board.

On Monday morning last Joseph Bowley, a builder, was fined 4*l*., and 15*s*. costs, for failing to give notice of intention to build, and deposit plans with the surveyor, according to the by-laws.

THE PRESERVATION OF WOOD.

IN order to protect organic substances, for some time at least, against putrefaction, they are, as is well known, impregnated with salt. This process, according to Dr. Krätzer, may also with advantage be applied in the preservation of wood. It has been noticed as a matter of fact that timbering supporting the roofs of salt-mines remains quite unchanged for some considerable time. Cooking salt or common cattle salt recommends itself, therefore, as the cheapest and most practicable means for preserving posts, piles, and, indeed, any woodwork exposed to damp, so as to prevent its rotting in the ground. Cattle salt is solved in warm water to saturation. Into this concentrated solution the wood, which must be well dried, is put, if not of too large dimensions, and left in it for a certain time. Scantlings of large size are coated with the solution until the wood no longer absorbs any more. Posts and piles driven into the ground are best surrounded with a layer of salt, which on its solution soaks into the wood and thus preserves it. Wood thus treated possesses also the advantage of not being attacked by insects or worms.

THE SURVEYORS' INSTITUTION.

WE hear from the Council that the Institution of Surveyors has now been incorporated by Royal Charter, under the above title, by Letters Patent under the Great Seal. Members of the Institution will, in future, be denominated Fellows, with the right to use the designatory letters F.S.I. after their names. The class of Associates is to be subdivided into two classes, Professional Associates and Associates. Present surveyor-Associates are to be placed in the former of these two classes, and are accorded the right to use the distinctive letters P.A.S.I. after their names.

Provision is made for the gradual introduction of the system of examinations for all classes of members which has already been foreshadowed in the education scheme for students, in operation for some time past.

SMOKY CHIMNEYS.

SIR,—I should be much obliged if you could give me any information as to where I could find any particulars about an invention, mentioned in the *Builder*, for curing a smoky chimney, by applying fine wire gauze in front of the fire-place, the atmospheric pressure preventing the smoke from penetrating the gauze. The book in which I saw it mentioned was published ten years ago. J. H. BALL.

*** We are not able to refer, nor does it seem necessary, the suggestion being complete in itself. We print the note, so that any of our readers who may have tried the experiment may tell us the result.

OBITUARY.

The Late Mr. Rendle.—We regret to have to announce the death of Mr. William Edgcumbe Rendle, of Westminster (formerly of Plymouth), who expired on the 3rd instant, at Eastbourne, after a long and severe illness, and who was interred on Thursday last at the Brompton Cemetery. He was born at Compton Giffard, near Plymouth, on February 10th, 1820. He was engaged in several large mercantile pursuits, and was patentee and inventor of what is now known as Rendle's Patent Glazing, which is adopted by H.M. Government and all the leading railways, his latest and largest work being the great Citadel Station at Carlisle. He was also successful in theatrical matters, and was partner with Mr. Augustus Harris, at Drury-lane Theatre, when "The World" was produced. He was also lessee of the Imperial Theatre, Westminster, and proprietor of the Clarendon Hotel, Brighton.

COMPETITIONS.

Darlington Board School.—At a recent meeting of the Darlington School Board, called for the purpose of considering competitive drawings for proposed additions and alterations to the Bank Top Schools, the design of Mr. G. G. Hoskins, F.R.I.B.A., of Darlington, was unanimously selected. The competition was confined to architects resident in Darlington.

Fulham Union Infirmary.—Designs in a limited competition for a new infirmary for the Fulham Union, at Hammersmith, have been sent in. The estimated cost is about 40,000*l.*

BASINGSTOKE BOROUGH SURVEYORSHIP.

SIR,—Being perfectly disinterested in the above appointment, I feel I can say a few words as to the very unfair way in which it has been made, and at the same time show those gentlemen who were applicants how their applications and testimonials were treated. The usual monthly meeting of the Town Council was held on the 1st inst., and after a few preliminary matters had been settled, they proceeded to elect the surveyor. The 129 applications were opened before the meeting, and the name and residence only of each were read. The ex-mayor remarked that he thought they ought to select (say) half a dozen names from those whom they knew, and who lived in the vicinity of the town, and choose from them; but this was not the general opinion of the meeting. However, the present surveyor's foreman was proposed and seconded, and as an amendment another local candidate, in the shape of a gentleman who has a stonemasonry business in the town, was also proposed and seconded, and upon a division the foreman had it by a majority of three, and was declared by the mayor to be duly elected. IMPARTIAL.

*** A more shameful proceeding of the kind never took place. The gentleman elected may, for anything we know to the contrary, be a thoroughly proper man for the post, but the Town Council, having induced a large number of gentlemen to become candidates, ought to have considered themselves bound in honour to examine their testimonials and weigh their merits.

STONE.

SIR,—Referring to your paragraph as to Messrs. W. H. & L. Collingridge having announced the completion of their new building, 148 and 149, Aldersgate-street, I beg to call the attention of your readers to the beautiful façade of the said building, which is of Red Corsehill Stone. SAMUEL TRICKETT.

BATS.

SIR,—Can any of your readers inform me how to expel bats from the inside oak roof of a church?

EDWARD STORY.

New College of Practical Engineering.—A new College of Practical Engineering has been opened at Muswell-hill, near London, under the auspices of a number of practical engineers in the kingdom, among whom we may mention Sir John Anderson, late chief engineer at Woolwich; Sir Henry Bessemer, inventor of the Bessemer process; Sir R. M. Stephenson, founder of railways in the East; and many more. The principal of the college is Mr. John Bourne, C.E., well known by his works on the steam-engine and other kindred subjects. The instruction given will combine theory with practice. One main distinction which its teaching will present is that there will be no cramming, and that everything taught will be permanently and practically useful. Another special feature will be that a number of treatises illustrative of engineering art will be produced at the college, forming together an engineer's library. The hands of the students will be educated as well as their heads.

Books.

The Purchase of Gas and Water Works. By ARTHUR SILVERTHORNE, Consulting Engineer. London: Crosby Lockwood & Co. 1881.

THE Statistics of Gas Undertakings under the Management of Local Authorities, and of London Gas Undertakings under the Management of Local Companies, in the first part of this book; and the Statistics of Water Undertakings under the Management of Local Authorities, and of London Water Undertakings under Local Companies, in the second part, will be found of great use. These have been collected with care, and Mr. Silverthorne, in his preface, acknowledges the assistance he received from the Local Authorities, without whose co-operation much of the information could not possibly have been brought together. These returns afford pregnant texts for disquisitions.

VARIORUM.

ACCORDING to the *Press News*, a very fine work on the City of Paris is now in the press, and is to be published in a thick folio volume as the end of the present year. It is divided into a number of monographs, the compilation of which has been entrusted to some of the most prominent amongst living French authors, together with a list of specialists in Art, Science, and Literature. The various sections are headed "History, Streets and Promenades, Opera, Parisian Fashions, Theatres, Monuments, Life in Paris, High Life, Eating and Drinking, Clubs, the Press, Sport, Political Life and Institutions, Palace of Justice and the Bar, the Water, Prefecture of Police, Artistic Life, Art Collections, Paris from a Balloon," &c. More than 700 illustrations on wood and in zincography and chromo-lithography are to accompany the text.——Cassell's *Popular Educator* gives an explanatory sentence on Engrossing:—"Amongst lawyers the term *engrossing* means the making of a fair copy of any document on a paper or parchment in clear and distinct characters, or, in other words, to transcribe in a legible manner the rough draft of any deed that has been prepared for transcription by a lawyer or barrister. This knowledge will help us to ascertain the meaning of the word *engross*. It is derived, as a little examination is sufficient to show, from the French proposition *en*, in, and the adjective *gros*, large. The expression *to engross*, in its literal acceptation, means to make large, and therefore distinct, as the larger in reason are the characters in which a document is written the more distinct and legible they are. Hence the word *engross*, which, in its primary sense, merely means to make large, has taken a secondary meaning, namely, to copy writing in large or distinct characters: and we can also trace the force of the simple and original meaning in a third signification that has been assigned to the word, when we speak of a person who is occupied in some absorbing pursuit as being wholly engrossed in his occupation—his employment, be it what it may, having taken such a hold on him, and assumed such large proportions in his mind, that he has little or no room there, if we may be permitted to use the expression, for other thoughts."

Miscellanea.

The National Standard Land, Mortgage, and Investment Company, Limited.—The objects of this company, advertised in our present number, include the purchase, sale, and development of large or small estates; the advancing of money on land and buildings, or on debentures and other securities; and the erecting of houses and buildings, and draining or improving the same. The prospectus shows, from an examination of the balance sheets of existing and land investment companies, that considerable profits may be looked for from this class of business if properly conducted. Mr. Edmund Woodthorpe, F.R.I.B.A., is surveyor to the company.

Cardiff.—The new Board of Trade offices have been opened at Cardiff Docks. They were built by Messrs. Kirk & Randall, Woolwich, to designs by Mr. Rivers, surveyor to the Board of Works, and form part of a Government block of offices, including postal and telegraph departments, erected at a cost of 14,000*l.* The site cost about 5,000*l.* in addition.

Sluicing the Pluckington Bank, Liverpool.—The works for carrying out this operation, upon which we commented a short time ago, are now practically complete, and very soon their effectiveness will be put to the test. The *Liverpool Daily Post* thus describes the works which have been executed:—From the George's Dock to the river wall immediately at the back of the George's Stage there is run through the Pierhead an immense pipe or culvert 10 ft. in diameter. This is for the conveyance of water from the dock to the sluicing apparatus, which is constructed at a lower level along by the river wall. There is at the end of this culvert a means of stopping the overflow of water, and this apparatus is worked from the Pierhead. Extending from this monster pipe there is another pipe of almost equal dimensions branching off from it at right angles, which traverses the shore at the back of the George's Stage. From this pipe there are twenty-two subsidiary pipes or outlets running at right angles to it and in the direction of the stage. The diameter of each of these pipes is 4 ft.; the length of each pipe is 45 ft.; and they are laid at a level of 10 ft. below the old dock sill. Each of the sluices is provided with a "clough" or dam, so that the water may, if necessary, be shut off from them. Thus they can be all worked, or only such of them as shall be deemed expedient. Such is the construction of the sluicing apparatus by the aid of which it is hoped that the Pluckington Bank will be washed away. The water available for the sluicing operations is by no means limited to that of the George's Dock. The whole line of the south docks can, if need be, be brought into requisition for the purpose.

Growth of a Co-operative Society.—An interesting account of the progress of the Wholesale Co-operative Society has been published by the *Manchester Guardian*, and some of its particulars are worth reproducing for the lesson they convey. The society was established in 1863, and is a federation of retail co-operative societies carrying on business all over England and Wales. At its start it had a capital of only 999*l.*, and did business in its first year to the extent of but 5,962*l.* Only forty societies were embraced in it, with an aggregate membership of 17,545*l.* According to its balance-sheet, made up at the 25th of June last, 618 different societies have now got shares in it, and 778 purchase their goods through it. Its capital, share, loan, and reserve, is now 563,907*l.*, and the last quarter's sales amounted to 862,000*l.*, those for the whole year being 3,389,000*l.* During the seventeen years of its existence this society has done a business of nearly 28,000,000*l.*, at a cost of only 362,786*l.*, or 1*l.* 8*s.* 1*d.* per cent., its net profits in the same period averaging 1*l.* 4*s.* 2*d.* per cent., which was enough to pay the 5 per cent. fixed interest on the capital, and an average dividend of 8½ per cent. in addition. The society has buyers in Ireland, Rouen, and New York, and latterly in Copenhagen; and it possesses two manufactories of boots and shoes, one in Leicester and one in Heckmondwike, but these have caused some dispute as to the allocation of profits, the workmen declaring that the profits of labour ought not to be divided on the same basis as the profits of the distributing trade.

Wesleyan Orphanage.—An addition to the benevolent institutions of the Midland district is about to be made by the erection of a Wesleyan orphanage near Erdington, Birmingham. Some time ago Mr. S. Jevons, a former resident in Birmingham, and one of the trustees of Sir Josiah Mason's Orphanage, offered to subscribe 10,000*l.*, if the Wesleyan Conference would vote a similar sum from the Thanksgiving Fund for the purpose of erecting an orphanage for the children of Christian parents. The offer was accepted, and 18 acres of land have now been purchased at a cost of 2,700*l.* in the neighbourhood of Oscott College. It is intended to begin building operations within a short period, and it has been decided that the institution shall consist chiefly of small detached homes, similar to others under the superintendence of the Rev. T. B. Stephenson, in Bonner-road, Victoria Park, London.

Safety Tap.—Messrs. John Warner & Sons, of Crescent Foundry, Cripplegate, tell us that their Mr. Goslin has just invented a safety tap for close boilers, kitchen ranges, and hot water heating apparatus, which, amongst its advantages, can be regulated to suit any and every pressure.

The Metropolitan Gas Companies.—A Parliamentary paper has been issued giving the results of the working of the metropolitan gas companies for 1880. It appears that the total capital and borrowed money of all the companies is 13,025,955*l.*, the Gaslight and Coke (the largest gas company in the world) standing for 9,469,943*l.*, the Commercial for 745,845*l.*, the London for 858,675*l.*, and the South Metropolitan for 1,951,490*l.* The total income from all sources was in the case of the Gaslight and Coke Company, 2,615,979*l.*; Commercial, 316,440*l.*; London, 315,036*l.*; and South Metropolitan, 745,842*l.*, or a total of 3,993,298*l.* The gross profit of the Gaslight and Coke Company was 899,909*l.*; of the Commercial, 102,224*l.*; of the London, 69,615*l.*; and of the South Metropolitan, 221,935*l.*; together, 1,293,684*l.* On capital and borrowed money this profit was equal to 9*l.* 10*s.* per cent. in the case of the Gaslight and Coke Company, 13*l.* 4*s.* 2*d.* per cent. in that of the Commercial, 8*l.* 2*s.* 2*d.* in that of the London, and 11*l.* 7*s.* 6*d.* in the case of the South Metropolitan,—the average of the whole being 9*l.* 18*s.* 8*d.* per cent.; while on the gas rental the profit per cent. was 45*l.* 7*s.* 2*d.*, 43*l.* 4*s.* 11*d.*, 29*l.* 4*s.* 1*d.*, and 40*l.* 4*s.* in the case of the four companies respectively.

Condition of Athens.—An alarming outbreak of typhoidal fever in Athens is reported, without much surprise to those who know the disregard of sanitary precautions practised there. The *Times* correspondent says:—"The mayor, who has certain duties still permitted him, in his anxiety to keep up the water supply through this exceptionally hot summer had turned into the main reservoir a stream in which the washerwomen of Cephissia have had from time immemorial their washing pools, and where is washed the linen of Athens, with its hospitals, civil and military; and the streets of the city, the windiest and dustiest in Europe, have been sprinkled with its waste waters, so that the dust, even, is charged with the desiccated matters contained in this waste water. If nature had not provided Athens with the purest air and the most salubrious position possible, the plague would have made its breeding-place here long ago." The authorities are moving in such directions as they may; but until the hot season is over, and the rains return in the latter part of September, or possibly not before the middle of October, nothing, it is thought, can be done effectually.

Statue of Marco Polo in Venice.—A statue of Marco Polo, discovered in Canton, has been received at his native city, Venice. It is life-size, made of wood, and gilt. According to a foreign contemporary, the famous Venetian traveller is represented seated, wearing the Chinese attire, although the cloak and hat are after the European fashion. His moustache and beard, which surround his face, are tinged dark blue, and while the Chinese artist has given him a peculiar form, the features in no way resemble those of a Mongolian type. Opposite the large red easy arm-chair, upon which Marco Polo is seated, is placed a porcelain bowl, intended to receive perfumes with which he was honoured in the same manner as is the protecting genius of China in the temple of Canton. The statue has at the foot an inscription in Chinese characters.

Window, Mansfield. — Messrs. Pitman & Son, 30, Newgate-street, have executed a stained-glass window for the west end of St. Chad's Church, Stuffynwood, Mansfield, Notts. It is a three-light window with lancet heads and tracery. The centre compartment contains a figure of St. Chad, robed in episcopal vestments, holding in one hand a pastoral staff, and in the other the model of a church. He was Bishop of Lichfield (on the borders of which diocese this church stands), and according to the calendar of the English Church, March 2nd is St. Chad's day. The side windows are filled with geometrical designs in leaded glass.

Dover Priory Gateway.—We have received a somewhat intemperate letter from an "Inhabitant of Dover" complaining of the substitution of an eminent London architect in the restoration of the Priory Gateway (for the purposes of the Dover College), for the local architect who has always acted for the college. Doubtless there were sufficient reasons. Anyhow we decline to print the letter.

Royal Manchester Institution. — The annual exhibition of modern works of art here, the sixty-first, was opened to the public on the 7th inst.

New Wesleyan Chapel, Walton-le-Dale. The corner-stone and memorial-stones of this chapel have been laid. The site contains 519 super. square yards. The style is Gothic. The building is to be of brick, with stone dressings, having ornamental brick panels in the gable and in other parts of the structure. The internal woodwork will be of pitch pine, stained and varnished. The roof will be open timbered, having carved and moulded principals. The dimensions of the chapel will be 52 ft. 3 in. by 29 ft. There will be a transept on the east side, a chancel measuring 19 ft. by 9 ft., and a vestry in the rear. The whole contract, including the pulpit, heating apparatus, gas-fittings, railings, gates, &c., has been let to Mr. H. Ward, of Preston, for 1,277*l.* 19*s.* 4*d.* The architects are Messrs. Myres, Veevers, & Myres.

Singular Cause of a Fire.—Some time ago the suspension-bridge of Mr. Roebling, crossing the Alleghany, near Pittsburgh, U.S., was almost destroyed by fire. At first it was found impossible to discover how the bridge could have caught fire. Further investigation has led to the conclusion that it arose from the fact that thousands of sparrows had been in the habit of building their nests of hay and straw in the interstices of the woodwork of the under portion of the structure. The conflagration was caused by sparks from the chimneys of the steamers plying upon the river beneath lodging in and kindling some of these nests.

The Parkes Museum.—This museum is closed till October, when it will again be opened free to the public on Tuesdays, Thursdays, and Saturdays; and during the winter, lectures on sanitary science will be given in the museum, illustrated with the appliances deposited in the museum, and many contributions sent from the recent exhibition at South Kensington. We believe it is intended to distribute the awards to the exhibitors at the public annual meeting of the subscribers to the museum in October or November.

New Sunday Schools at Kidderminster are about to be erected by the Baptist denomination, from plans prepared by Messrs. Ingall & Hughes, architects, Birmingham. They provide a spacious central room for massing the children at the opening and close of the schools; also twenty class-rooms, — ten downstairs and ten upstairs, — opening into a gallery round three sides of the room. The builder is Mr. R. Thompson, of Kidderminster, the amount of whose contract is 1,989*l.* 10*s.*

Liverpool and Southport.—Of the new North Docks (opened by H.R.H. the Prince of Wales on Thursday last), of the Royal Court Theatre (to be opened this Saturday, the 10th), and of other new works in Liverpool, as well as of the new market at Southport opened on Wednesday last, we are compelled by exigencies of space to postpone particulars to next week.

Surveyors' Salaries, Eastbourne. — The salary of the town surveyor of Eastbourne (Mr. Charles Tomes) has been raised by 100*l.*,—from 275*l.* to 375*l.* The salary of the building surveyor (Mr. E. W. C. F. Schmidt) has been increased by 35*l.*

Art Director.—We are informed that Mr. Thomas Armstrong will succeed Mr. Poynter, R.A., as Art Director at South Kensington, and Mr. Sparkes (now head-master) as Principal of the National Art Training School.

Fine Art Exhibition at Bolton.—A fine-art exhibition, in aid of the Bolton Infirmary, was opened in the new buildings of that institution on the 5th inst.

The New Townhall at Hastings was opened on Wednesday, the 7th inst. In our last volume (pp. 570, 572) we published a view, plan, and description of the building.

TENDERS

For the erection of a school residence for young ladies, at Goudhurst, Kent, for the Rev. J. J. Kendon. Mr. Wm. Theobalds, architect. No quantities:—

Fowler	£1,067 0 0

Decoration of the Central Hall, Houses of Parliament.

ABOUT a month since we made note of the recurrence of one of those little passages of arms on an artistic question which occur now and then in our legislative assembly, just to remind its members, apparently, that there is such a thing in the world as art. It is true that whenever such discussions are raised we hear that the House was very empty, and the discussions are usually carried on by two or three members who habitually profess an interest in art, and who are nearly certain to be heard if any such subject is raised. As a general rule, it may be added that the art-critics of the House are pessimists, and that they are usually in opposition to anything whatever that is proposed, not because they are indifferent, but because, according to their account, everything is so hopelessly bad in modern art that it is no use doing anything at all.

The particular discussion we refer to was raised (on the 16th of August) by Mr. Schreiber, in reference to the three panels in the Central Hall which are still left blank, wanting the pictorial designs, of some kind, which they were intended to receive. Mr. Schreiber called attention to the fact that the completion of the decorative scheme of the Central Hall had been left in abeyance for twelve years, except in regard to the one panel occupied by the mosaic reproduction of Mr. Poynter's fine design of St. George. Mr. Schreiber intimated that he did not intend to let the question alone, and before the House separated for the recess he wished to know whether the Government had any policy in regard to the Central Hall, and if so, what it was. Referring to the partial failure and great tendency to decay exhibited in some of the frescoes, he disclaimed any intention to ask for money for the completion of the decoration in that medium, which had led to so much disappointment. Besides, the decoration scheme might now be said to be "under the mosaic dispensation," one mosaic picture having already been executed. Mr. Schreiber said that having been absent from the House for twelve years he had been much disappointed to find after all that time the decoration of the Central Hall still unfinished; and he had asked the late Mr. Adam when it was intended to complete it, and whether he was in possession of the designs for the three vacant panels. The reply seems to have been, like the panels, a blank: all that was elicited was that there had been much discussion about the matter in 1870-71, but that no definite conclusions had been arrived at. Whether designs for the three panels had been made, or were in possession of the then Commissioner of Works, did not appear. Mr. Schreiber said he intended to press the point next Session, and if he did not then find that Mr. Poynter had been commissioned to prepare a design for "St. Patrick" he should appeal to the patriotic feelings of the Irish members in regard to the exclusion of their patron saint from the House. That it would be necessary to get up some such side-play on the subject to awaken any real interest in it, is, we fear, likely enough. Mr. Schreiber concluded for that occasion with a motion that the decoration of the Central Hall, interrupted twelve years ago, should be resumed and completed in mosaics.

So far Mr. Schreiber, on the occasion in question. It remains to consider what response was elicited by this well-meant proposition, and what, as far as our judgment goes, is the real truth of the matter. As far as any ostensible response was elicited at the time, it was almost entirely of a negative character, and was confined to some criticisms by Mr. Cavendish Bentinck, and the reply of the First Commissioner, Mr. Shaw Lefevre. The remarks of the former gentleman showed little thought or consideration, and were only too typical of the tone frequently taken by the few amateur art-critics who are numbered among our Parliamentary representatives. According to Mr. Bentinck, everything to be had was so bad that it was useless to do anything. All the frescoes in the House were failures, all the mosaics that had been executed in England were failures, including the mosaic picture of St. George, already executed. The remedy, according to Mr. Bentinck, was to do nothing. The mosaics in St. Paul's, by two of the greatest living artists, were total failures, and an awful warning against attempting anything of the kind. The most original reason, however, for Mr. Bentinck's let-alone policy was that the decoration of great national edifices had never been finished at once,—it had always been the work of many generations. The argument seems to be, therefore, no decoration that is worth anything can be accomplished unless it is allowed to drag out in a similar manner. It would be waste of time to bring counter-arguments against such logic as this.

The reply of the First Commissioner resolved itself into this,—that the existing mosaic had not given satisfaction; that the artist had, in fact, wished to have a portion of it cut out, in order to be better carried out *de novo* (this would seem to imply that the dissatisfaction was with the execution, not with the design); and that the committee of artists, called together by Mr. Ayrton (ominous name in connexion with such a subject), which included Messrs. Poynter, Pope, Herbert, and Armitage, had recommended that the remaining panels should be filled in with fresco. Having in view the generally unsatisfactory opinion about the existing frescoes in the House, he could not feel justified in asking for a vote for the fresco scheme. In regard to the mosaic scheme he considered it would be very undesirable to go into that, unless there were an assurance that the work executed would represent the highest art. The breaking up of the mosaic school at South Kensington had deprived them of one means of obtaining the execution of the work, and in the present unsatisfactory state of mosaic art, it would be better to leave the panels incomplete. Result,—motion negatived.

It is exceedingly unsatisfactory and annoying to find this sort of tone taken in Parliament on what seems a most reasonable proposition to make some endeavour to worthily complete the decoration of what is architecturally the finest portion of the House. Before considering the main subject, we may observe that we by no means admit the *dictum* of Mr. Bentinck that the mosaics in St. Paul's are entire failures, nor do we know very well why the public or the House should be expected to take his word for it. We have always held that the introduction of such colossal figures into the architecture of St. Paul's was a very questionable expedient, inevitably dwarfing the scale; but that is beside the question. As mosaics, the two figures by Mr. Watts and Mr. Stevens are certainly worth something better than to be dismissed so cavalierly. Now in regard to the existing mosaic in the Central Hall at Westminster, it is under two decided disadvantages inseparable from its position, or almost inseparable. In the first place, it is on a flat surface, whereas mosaic is always most effective on a more or less concave surface, which by its diverse reflections brings out the brilliancy of the material. Secondly, it is in the daytime under a shadow formed by the deep reveal and archivolt of the arch which makes the framework to the panel; and the light being subdued by stained glass and admitted rather high up in the walls, there is only a very moderate amount of direct light upon the picture, and a considerable shadow thrown downwards over it from the upper portion of the arch. Our last inspection of the work was on a very dull day, which made the defects of the position more remarkable than usual. On a bright day it would show much better; and under artificial light, in which it must be viewed for at least a large proportion of the period during which the building is fully occupied, there is certainly nothing to prevent this and all the other panels, if similarly filled, from being well seen.

The difficulty in the daytime, in regard to effect, lies partly in the fact that the windows are filled with tolerably strong-coloured glass.

It should have been recognised at first that strong effects in polychromy cannot well be carried out on walls and in windows in the same apartment. For a perfectly satisfactory effect, you must choose between coloured decoration by reflected light and coloured decoration by transmitted light; both cannot be equally effective in the same place. There must, in the case of wall decoration by reflected light, be sufficient light admitted through the windows to give brilliant reflections; and the want of this is the drawback in the Central Hall. But still, this defect is only seriously felt on dull days, and is not in itself sufficient to furnish a reason for letting the matter alone altogether, and leaving these dull blank places in the generally rich design of the Central Hall.

We urge strongly, therefore, that the panels ought to be completed, that the action of the Member who drew attention to it before the close of the session was very opportune, and that something more ought to be heard about it when Parliament meets again; and there can be no doubt that when carried out, the new designs ought to be carried out in mosaic, the same material in which the present panel is executed. In regard to this point, we read with astonishment the statement that four artists, called in by Mr. Ayrton to enlighten his mind on the subject, recommended that the remaining panels should be treated in fresco. Surely these gentlemen must have based their recommendation on a supposition that the panels would never be seen sufficiently to distinguish fresco from mosaic; otherwise it is inexplicable how they could have recommended the juxtaposition of two such very opposite methods in the same apartment of a building. The whole design of the Central Hall is absolutely symmetrical, and to place on one face of it a mosaic with its reflecting surfaces and rich colour, and on the other three faces frescoes with their dead surfaces and necessarily rather low colours, is such an absurdity that we can hardly believe that four artists recommended it, and can only say that if they did, their ideas as to the relation of pictorial decoration and architectural effect must have been very hazy.

As to the prevalent opinion, for such we believe it is, that the large number of existing frescoes in the House are failures, a word may be said here. That the frescoes gave much trouble in regard to material failure every one knows; and the difficulty was, perhaps, in itself sufficient to deter any one, from a mere commercial point of view, from voting money to pay for more work of the same type. In regard to artistic effect, the frescoes in the House are, however, also in great measure failures, owing to defective æsthetic or bad position, or both. The two great paintings by Maclise, in the Royal Gallery, whatever degree of success they may be considered to have as paintings, are completely wanting in reference to the architectural design. They are obviously colossal afterthoughts; they are either too long for the gallery or not long enough; they should have either run the whole length of the walls, or they should have been confined to a well-marked central space, which should have appeared to be naturally left for such decorative treatment by the arrangement of the architectural design. As it is, they only suggest that two immense paintings have been got into the room, which have no necessary relation to the architectural scheme of the interior, and which it is impossible for any one perfectly to see either in regard to distance or lighting, for the light is for this purpose nearly as bad as it can be, it being impossible to look up at either painting without the eye being annoyed by the window over it, while the two cross-lights mutually interfere with each other on each painting. The moral is that when it is intended to introduce important paintings on a large scale as a permanent decoration to an interior, the architecture and the lighting should be designed from the first in reference to the painting. The frescoes in the corridors are better off in one point; they are distinctly prepared for in the architectural design, and form an integral part of it, or, at least, its necessary complement. The panels are prepared for the reception of a series of designs, and they fall naturally into their place. But there, again, are some failures in effect, partly from the same cause as in the Royal Gallery, the cross-lighting; which, coupled with the glazing that it has been found necessary to put over them, renders it exceedingly difficult to see them at all. There is also a mistake inherent in at least a good many of these works, viz., that the treatment is too distinctly pictorial,* either for the capabilities of fresco or for the position of the paintings in relation to the architecture, and that a degree of realism is attempted in some of them which cannot be satisfactorily attained in fresco, and consequently impresses us with an idea that the artist has missed his aim, and that the execution is coarse and unsatisfactory. This would have been avoided if a flatter, more conventional, and less pictorial treatment had been adopted, as would certainly have been done had the work been commenced now; but at the time these frescoes were commenced the value, and even necessity, of a certain marked conventionalism in such a situation, and with such a method, was not understood as it is now. It must be admitted, however, that even then there would have been difficulty in meeting the natural demand for historical truth of costume in paintings intended as representations of facts in the history of England, while preserving the conventional style.

It is in this sense that we agree that the frescoes in the House are to a certain extent failures is regard to their main object as decorative art. The difficulty in regard to realism would not be felt in reference to the class of subjects with which the large panels in the Central Hall are proposed to be filled. So far as that goes, fresco would be a very suitable medium for such designs as the St. George of Mr. Poynter, and others in a similar style and spirit. The reasons against it are, first, that the other frescoes have shown such great tendency to rapid decay (a consideration which from a commercial point of view, we must expect would impress itself strongly on members of the House who have seen these works peeling off before their eyes); secondly, that the one panel is now executed in mosaic, constituting a very fine design, to the merits of which the art-critics of the House seem remarkably blind; thirdly, that the very rich decoration of the vault and walls of the Central Hall requires mosaic as its highest point, and that the comparatively dull surface of fresco would be killed by the general effect of the apartment, and more especially by the stained glass. That the stained glass is an impediment to the effect even of the mosaic by stopping out too much light, we have already said; but as the glass is there and is not likely to be deliberately taken out again, there is no question that mosaic is the form of mural decoration which is best calculated to hold its own against the effect of stained glass windows, and that it is, in fact, the only form of wall decoration which it is worth while to introduce in the positions in question.

The objection that there is not English talent available at present to execute mosaic in a high style, if we are to admit the fact, certainly ought not to be taken as a reason for not proceeding with the work. We can at least go to English artists for the design, and if we cannot find in England the workmen, we must go elsewhere for them. Let it be observed, in conclusion, that the estimated cost of the three unfilled panels, reckoned on the basis of the already completed one, is only about 2,000*l.*; and it is surely not to be supposed that any large proportion of educated tax-payers would consider that an extravagant or unjustifiable outlay for completing the decoration of the central point of the national legislative building, even if circumstances preclude us from getting all the effect which we might wish to obtain. The incomplete state of the Central Hall is not creditable to us, either to our spirit and liberality in many matters, or to our artistic feeling; and though this latter element is, we fear, by no means well represented in the House (inasmuch as people are not elected to Parliament on account of their artistic culture), there must surely be a large section of the constituencies who would quite approve of going to some little expense in completing the decoration of a part of the House, in which, as it is a public place in time of session, they have as much direct interest as members themselves. We hope the point will be brought up again and satisfactorily settled next session. We have only recently recorded (see page 279, *ante*) the completion at Aix-la-Chapelle of an important work in mosaics, and the interest which the accomplishment of the work has excited in Germany. The state of our Central Hall at Westminster, and the apparent indifference of the Legislature about it, contrast ill with the account we then published.

* Some few of them, as will be remembered, are actually reproductions of oil-paintings, with very unsuccessful result when compared with the original paintings.

ELECTRICITY AND OUR FOOD SUPPLY.

THE most wonderful and important discovery yet made by man is, there can be no dispute, that of the mutual convertibility of the chemical, physical, and electric forces. We are not speaking of any single effort of imaginative genius, or of the mass of the contributions to science offered by any single pioneer of the army of discovery. Little by little the great truth has become clear. Little by little has the veil of Isis been raised, and the motto which is now being cut, in hieroglyphics more luminous than those which identify the mummies of Egyptian kings and conquerors, is in the terms, "TO MOVE IS TO BE."

In the later years of well-earned leisure enjoyed by George Stephenson, when the great engineer was devoting many hours to the task, long seeming impossible, but ultimately accomplished, of making cucumbers grow straight, no topic was ever more grateful to the inventor of the locomotive than that of the manner in which the provender for the iron horse had been stored up by the prehistoric agency of the sun. By encouraging that rich and copious vegetation which purified the atmosphere of our planet from a large amount of carbonic acid, or, at all events, of some volatile form of carbon, the sun was at work for millions of years in imprisoning in woody tissue that free energy which was accumulated, compressed, and stored in coal. The pick of the Northumbrian collier was the weapon by which that rich store of solar heat and light was rendered accessible to the toilers of the nineteenth century; and the stationary engines, of which Watt was the founder and first producer, no less than the locomotive engines perfected by Ericssen, Stephenson, Brunel, and their lieutenants, owed their life and play to the vegetation of the great carboniferous age.

Those of us who have seen with our own eyes the introduction and the improvement of the locomotive, are those who are most profoundly impressed with the immeasurable significance of the strides that have been made since that time in the study of dynamics. We do not so much refer to the development of mechanical improvement, as to the growth of the conception of the unity of force; for, great as mechanical progress has been in the last half-century, and increasing as is the daily rapidity of its development, it is evident that entirely new lines of advance are opened to the genius of man by the discovery of the master secret of mechanics. And the Faure battery, the efforts of Colonel Beaumont to utilise compressed air as a convenient motor,—indeed, the whole range of invention that deals with dynamo-electricity,—are but the first steps taken to reconnoitre and to survey this new province in the kingdom of Science.

It is impossible to give a more striking proof of the pregnant promise of the scientific discovery in question, than is afforded by the fact that one of the most brilliant of contemporary mechanists has been wiled away from the pursuit of mechanics to devote a portion of his time to the opening of a new chapter in horticulture, arboriculture, and agriculture. Let any one read the full text of the address of Dr. Siemens to the British Association, on electric energy, to which we have already referred, and we do not envy him if he fails to catch something of the noble enthusiasm of the speaker. We live fast in these days. Our views change with the change of circumstances. What was regarded as colossal eighty years ago is now only rather large. A millionnaire is not now a man who stands in the first rank of wealth. Thus for what may be needful to establish a scientific reputation of the first order we are becoming yearly more exorbitant. But we do not hesitate to say that if the results of a study of apparently some two years by Dr. Siemens could have been attained only a decade ago, they would have been regarded as an ample and most brilliant outcome of the labour of an entire lifetime of a scientific man.

On the 1st of March, 1880, Dr. Siemens communicated to the Royal Society a paper "On the Influence of Electric Light upon Vegetation." During the whole of last winter he has continued his experiments on the subject on a large scale. We must refer our readers to the address itself for details, but we are anxious to give some faint idea, in block, of what has been already ascertained. As for what may come of it in the future,—the prospect is too vast to take in at the first view. It almost seems as if that which has been the dream of

the lifetime of Liebig, the production of human food by the chemist, was about to be realised by the genius of the electrician. If we cannot yet directly combine inorganic elements into matter that can be assimilated by organised beings, it seems, at all events, likely that we shall be able immensely to stimulate the combining action of organic life itself.

The horticultural experiments of Dr. Siemens were directed to the end of ascertaining the effect of a powerful electric light on the growth of plants. They were carried on in a glass house of 2,318 cubic feet capacity, and in some sunk greenhouses, of which the capacity is not stated. The stimulatiog energy applied was luminiferous —not thermic,—and the heat desirable for the growth of the plants was obtained from the waste steam of the engine which drove the dynamo-motors of two electric lamps of about 5,000 candle-power each. The experiments were carried on for 197 days, from the 23rd of October, 1880, to the 7th of May, 1881. The nominal power of the steam-engine employed was 6-h.p. The consumption of coal was 56 lb per hour, which makes a cost (at 20s. per ton) at 3d. per hour per light of 5,000 candles. This cost, however, has to be reduced by the value of the heat afforded by the spare steam, so that the net cost of the light in cases where water-power or even wind-power is available, would be infinitesimally small. To that part of the case, however, we may have hereafter to revert. The actual effect of the light is matter of incomparably more interest than its present cost in money.

Dr. Siemens planted in the glass house peas, French beans, wheat, barley, oats, cauliflowers, strawberries, raspberries, peaches, tomatoes, vines, and a variety of flowering-plants. He maintained an even temperature of about 60° Fahr. His first experiments were unsuccessful, the tender leaves of the plants being, as it were, scorched by the fierce artificial light. Not baffled by a check which might have discouraged any but a born inventor, Dr. Siemens proceeded to make experiments on the virtue of different hues of light, by transmitting it through variously-coloured, as well as through clear, glass. To his infinite delight, we should conceive, he found that a screen of clear glass was all that was required. Whether the products of combustion in the electric arc affected the plants injuriously or not does not seem quite certain, but that radiating influence was the main agent the careful and ingenious experiments have left no doubt. That there are invisible actinic rays at the most refrangible end of the spectrum which are poisonous to plants, and that these rays are arrested or transformed by passing through clear glass, may thus be stated as the first positive discovery wrought out from the experiments. And as to the colours of light, the order of merit is,—white light, transmitted through clear glass, yellow, red, and blue. A vigorous growth was attained by the plants lighted through the first. They became feeble and more imperfect, in the order given, until those exposed to the unguarded light showed a stunted growth, and a very dark and partly shrivelled leaf.

The electric light was kept on from five p.m. to six a.m. every night except Sundays during the whole experiment. Strawberries ripened under it on the 14th of February, pears on the 16th of February, raspberries by the 11th of March, and vines bore ripe grapes on the 10th of March. The size, beauty, and flavour of the fruits are described as unusually good. A banana, set within two yards of one of the glass-protected lights, bore a bunch weighing 75 lb., each banana in the bunch being of unusual size, and the flavour being declared to be unsurpassed. Melons, remarkable for size and aromatic flavour, were also produced in the early spring. We are not reciting a fairy tale. Dr. Siemens has already given hostages to science enough to justify the public writer in accepting with implicit faith the precise statements of a report bearing his signature.

Subject to that reserve with which the results of any wholly new power must always be in the first instance received, it really seems as if the problem of artificial horticulture had been definitely solved by Dr. Siemens. And as to cost, it is positively ludicrous to speak of it. For there seems small reason to doubt that, at all events with annual vegetables, the crops of three or four years may be certainly raised, by the aid of the electric light, from soil that now, under the most favourable circumstances, can only give an average yearly harvest. And if we take one maximum harvest out of three years, the increased value of the soil to the cultivator is octupled or decupled. These seem large figures, but they are the simple outcome of the data before us.

The next thing that strikes our attention from these experiments is, that the sleep of plants is an accident of the constitution of our globe, and that, though innocuous, and consistent with all that goes on in our alternation of day and night, it is not a necessity of their nature. The entire absence in plants of a nervous system at all comparable to that of the members of the animal kingdom, is an argument that such nocturnal rest is unnecessary. Indeed, it seems from the experiments that a nightly growth does actually take place, but a growth of stem and leaf, at the expense of flower and fruit. How far the winter rest may be necessary, we do not think that the experiments as yet illustrate. We have, therefore, spoken of annual plants alone.

As to the cereals, which, of course, form the great *point-de-mire*, the experiments have as yet been unsuccessful. We venture to think, however, that the failure is due rather to a want of knowledge of the exact conditions favourable to the growth and ripening of wheat, barley, and oats, than to the failure of the electric light to anticipate the rays of the sun. A low temperature at certain stages of their development is probably a necessity for the healthy growth of these plants. In the Apulian plains, where the finest wheat we have ever seen is grown, frost, though not severe, is not unknown, and cold winds from the snow-capped Apennines are frequent. The great thing for the growth of the cereals is the timely sequence of cold and heat, of moisture and of drought. The cases are rare when these are supplied in their exactly required order and proportion by nature; hence the rarity of the best harvests, and the frequency of poor ones. But let the annual biography or rather phytography, of the corn-plant be once known, let the proper hygrometric, calorific, and luminiferous conditions for each succeeding stage of its growth be once fully ascertained, and we see no reason why corn should not be forced by electricity, aided in due time by icy or by sultry blasts, with perfect and certain success.

Dr. Siemens concluded his most valuable paper by suggestions as to the application of electricity to perform the hard work of a farm, to plough, to thrash, to pump. Into that we cannot now follow him. Not that these applications of the electric force are less interesting, but that the idea of the dynamic husbandry is more so. The field is so new, as well as so vast. And the interest which the invention should command is intensified at this moment by the condition of British agriculture. The harvest that was to make up for a series of bad years seems to be eluding the farmer daily. Only 8,875,702 acres of land in Great Britain were under corn crops in 1880, as compared with 9,675,261 acres in 1871. In Ireland there were 1,766,424 acres under corn in 1880, 2,124,079 in 1871. Potatoes show a like decline. And all green crops, including potatoes, in Ireland, sank from an acreage of 1,511,532 acres in 1871, to 1,247,359 acres in 1880. In Great Britain the green crops covered 3,738,180 acres in 1871; 3,476,653 in 1880. The crops have fallen off in a far more rapid proportion, the monthly sales returned by the Board of Trade having amounted to 12,731,751*l.* in 1871, and only to 6,381,684*l.* in 1880. We do not wish to travel outside the proper limits of these columns. But facts are not opinions, and when, on the one hand, we take such ugly and menacing facts from the statistical abstract of the United Kingdom, and, on the other hand, mark the result of experiments that promise to make two, if not three or four, ears of corn ripen with certitude where now one ripens with hazard,—we think we are justified in calling attention to the paper of Dr. Siemens on about the most interesting subject as to which any Englishman can allow his imagination to indulge its reveries.

The Birmingham and Midland Institute.—The new wing of the Birmingham and Midland Institute, which has been necessitated by the great increase of students both in the industrial and general departments, is now approaching completion, and will be formally opened on the 20th of October, when Dr. Siemens, the president, will deliver the inaugural address in the Town-hall. The total cost of the new block is about 30,000*l.*

THE NEW ALEXANDRA DOCK AT LIVERPOOL.

AN occasion not unworthy of the presence and sanction of their Royal Highnesses the Prince and Princess of Wales was the opening, on the 8th current, of new dock accommodation, amounting to 110 acres of water-space, and more than 6½ miles of quay-berthing, in Liverpool. For the description of the spectacle and of the festivities our readers must turn to the local papers; for Liverpool has her own daily as well as weekly press, and is not content with a corner in the London morning newspapers. But we cannot pass over either the great engineering features of the extended accommodation given to the traffic of the Mersey, or the brief but exhaustive summary of the progress of the commerce of Liverpool, which was given by the Prince of Wales in returning thanks for the toast to his health at the luncheon spread in one of the sheds of the new docks on the occasion.

At the commencement of the present century, said his Royal Highness, dues were paid in Liverpool on 650,000 tons of shipping; at the present time they are paid on between 7,800,000 and 7,900,000 tons, an increase of twelve-fold. In 1846, when his Royal Highness the Prince Consort visited the town, and opened the Albert Dock (called after his name), the docks for the business of the port of Liverpool were twenty-seven in number; they are now fifty-eight. In 1846 the area of water in the docks was 122 acres; it is now 543. In the former year the length of quayage was 9½ miles; it is now 40 miles. In 1846 the extent of the dock estate was 506 acres; it now amounts to 1,545 acres.

To these important figures thus put on record from the lips of the Prince of Wales, it may be well to add some details which will allow of comparison between the growth of Liverpool, as a port, and that of the general commerce of the United Kingdom. In the year 1800 (taking a proportion of a decennial return), the total tonnage of vessels employed in the foreign trade cleared outwards to all parts of the world, including Ireland, from the ports of Great Britain, was 175,000 tons. In 1846 the total tonnage of British and foreign vessels cleared from the ports of the United Kingdom was 6,314,571 tons. In 1880 the corresponding tonnage was 18,903,530 tons. Subject to any slight correction as to the value of Irish commerce, the advance of our mercantile activity, as measured by the tonnage of vessels clearing from our ports, has been thirty-sixfold between 1800 and 1846, and threefold between 1846 and 1880. As to the growth of Liverpool during the first period, it was prodigious, for it was starting almost from nothing. During the second period, in which our general commerce was multiplied by three, the number of docks in Liverpool has more than doubled (multiplied by 2·15); the area of water-surface has more than quadrupled (or multiplied by 4·45); the length of quay-walls has also quadrupled; and that powerful and important body, the Commissioners of the docks, have rather more than trebled the area of the extent of their property. Certainly Liverpool has kept well to the fore in providing for the increase of our commerce.

In 1873 the development of the steam navigation of the port of Liverpool was such as to call for more accommodation than then existed. Plans were prepared by Mr. Lyster, the engineer to the docks, and Parliamentary powers were obtained to borrow 4,100,000*l.* on security of the dock rates, with which capital the new works were paid for as they proceeded. The entrances of the new docks, containing, as before stated, 110 acres of water, had their sills laid at a level which allows the general class of vessels frequenting the Mersey to enter at any state of the tide. The docks are situated at Bootle, 3½ miles seaward of the Royal Exchange of Liverpool. The principal entrance is through the Canada basin, a sort of *avant-port* to the most northern docks, in which the tide ebbs and flows freely. This basin itself has been considerably enlarged and deepened to meet the new requirements, and its entrance from the river has been increased from 380 ft. to 400 ft. in width. Timber jetties are now in course of construction on each side of this entrance, projecting into the river. That on the north side, which is complete, is a remarkable work, called the Horn pier. The river wall curves sharply outwards, and terminates in a massive iron-clad bastion or pier-head of granite. From this the jetty returns for about 40 ft., ending in another pier-head of concrete, from which an

arm is thrown out to the new wall. On the north end of the Horn pier is a look-out tower, and an iron standard 80 ft. high, for the display of the electric light. The jetty is supported by strong uprights of green-heart timber, let into a granite base. The form of the wall is intended to break the force of the waves which rush up the Mersey in stormy weather.

There are two passages from the Canada basin, giving entrance to the new docks. The first of these is the Langton Dock, with a water-area of 18 acres, and 4,000 ft. ran of quay or berthing space. On the eastern side of these docks are two graving-docks, each of which can be so divided as to accommodate two vessels of large size. Pumping-machinery for emptying the graving-docks is erected on the quays between them, as well as hydraulic machines for opening and closing the dock-gates, bridges, and sluices, and for working the cranes. The pumping-engines, in two sets, of 420 horse-power, are by Messrs. Hull & Son, of Bolton. The hydraulic machinery is worked by a 350 horse-power engine, by Sir W. G. Armstrong & Co. Rooms to accommodate the foreman and enginemen are arranged in flats over the engine-house; and there is a clock-tower 120 ft. high, which contains the accumulators.

On the east side of the Langton Dock is a branch dock, with three acres of water area, and 2,000 ft. of quay. On the south quay of this dock will be an hydraulic 100-ton crane. On the north side of the Langton Dock two passages lead into the Alexandra Dock, named after Her Royal Highness the Princess of Wales, who opened the same on the 8th current. The Alexandra Dock has been expressly designed for the accommodation of steamers of the largest size. It is 1,600 ft. long from north to south, and on its eastern side are three branch docks, ranging from 1,100 ft. to 1,338 ft. in length, which extend inland to the main thoroughfares of the Regent-road. Altogether, the water area of the Alexandra Dock and its branches is forty-four acres, with nearly 12,000 lineal feet of berthing for ships.

The walls of the docks are built of cement concrete, faced with red sandstone of the neighbourhood, and coped with granite. The entrance walls are faced with granite. The steps and slips of the graving-docks are faced with granite. The dock-gates are made of greenheart timber; a wood of great specific gravity, and considered to be extremely durable. The berthing quays are provided with storehouses, from 80 ft. to 95 ft. wide, for the protection of cargo in transit; and there is direct communication by rail from these sheds to the termini of the several railways, as well as by road to the city itself.

For those who care for omens, it may be added that a fine carving of the Royal Arms of Great Britain before the union with Ireland has been lately discovered in the King's tobacco warehouses, near the docks, having been removed from an old building on the Dock estate. The stone has been re-erected as a memorial of the visit of their Royal Highnesses, and a floral border has been cut to surround the escutcheon, in which the shamrock has been inserted, and by which the plumes of the Prince of Wales are conspicuous. On a granite slab is cut the inscription, "These Arms of Great Britain, in the reign of George III., were removed from an old building on the Dock estate, and are erected here as a memorial of the auspicious visit of their Royal Highnesses the Prince and Princess of Wales on the occasion of the opening of these docks, September 8, 1881."

The presentation of a silver trowel on the occasion of laying a first stone has been long justified by the convenient service afterwards to be rendered by that implement as a fish-slice. The Liverpool Dock Commissioners seem to have drawn practical wisdom from their study of the Arabian Nights Entertainment, or some other fairy tales; for the handle of the lever by which the Prince of Wales set in motion the machinery for opening the great sea gates of the docks, turned, after its function was accomplished, into a hunting-knife, which was presented to the Prince; and the gold and jewelled knife with which Her Royal Highness severed the silken cord to allow of the opening of the Alexandra Dock, was, screwed into the handle of a parasol, presented to the Princess as a souvenir of the occasion.

The Eastbourne Sanitary Exhibition, we learn, has been successful even in a financial point of view. The expenses were 425*l.*, and there is a surplus of 40*l.* to the good.

FROM GERMANY.

Artistic Progress.—Professor Mohr, of Cologne, has lately exhibited in the museum of that city a gilded drinking-vessel designed by him, and executed in cast silver by H. Gladenbeck, of Berlin. The *Kölnische Zeitung* remarks that of late years there has been a general want of independent artistic invention, with regard to ornamental art, and notably as to vessels and ornaments of gold and silver. The writer of the article remarks that the goldsmiths of modern times seem to have lost that appreciation of the finer technicalities of their art, which was possessed by the workers of the sixteenth century, and calls attention to the numerous opportunities modern times afford artificers in precious metals for displaying their inventive genius, as to the forms which their productions should assume. These opportunities, it is urged, are neglected by the goldsmiths and silversmiths of the present day, who usually confine themselves to executing designs furnished to them by artists not members of their craft. The modern system of division of labour seems also, it is said, to be unfavourable to that unity of design so essential to good effect, and which is the secret of the renown achieved by such masters of their art as Benvenuto Cellini.

Professor Mohr has been occupied four years on this work, having met with many interruptions. Besides numerous ornaments and masked heads, there are fifty-six figures produced by casting and chiselling. The length of the part which contains the figures is 24 in. On one side the pleasures and griefs of love are shown, and on the other the different effects of wine: the former is quite a romance. A cavalier is serenading his lady love, and on the appearance of a jealous rival a duel ensues, in which the lover is victorious, and the final subject represents the happy pair on their way to the bymeneal altar. The surrounding foliage contains allegorical and other objects in harmony with the jewelled work displayed. The other side portrays a young vine-dresser in a vineyard, and the vessel of wine lying near is supposed to have brought before him a fantastic vision. In the following picture he has become a cellar-master, and in harmony with the previous revelations as to his bibulous disposition, he is seen carousing in company with a soldier and a student. The succeeding group contains a moral, as the Evil One is seen rising in a sheet of flame from a cask of wine and looking for a victim. Numerous other figures of a subsidiary nature are included in these well-executed groupings. The central point of the vessel is formed by a wreathed head of Silenus, with the motto *Ad multos annos* (For many years).

The lid is in harmony with the minor ornamentation of the body, and represents Tritons, Naïads, and dolphins in their native element. The handles are in a similar style. The upper part of the lid consists of an allegorical figure, on which the arms of Cologne are introduced. The lower part of the vessel rests on richly-executed figures as bearers.

The Preparation of Estimates.—One of the technical organs of the glass trade in Germany recently called attention to the above subject, with special reference to a resolution adopted early this year by the Glass Corporation of Dresden. The following was the resolution in question:—"In consequence of the numerous demands for estimates of an extensive character, some of which referred to cases in which the execution of the work had already been practically arranged for, it is resolved that, in cases where estimates are not followed by orders, an amount will be charged in proportion with the trouble incurred." In commenting on the advisability of this step, the article points out that those who have contracts to give out are often very thoughtless as to the great amount of pains taken by each person sending in an estimate. It is suggested that ½ to ½ per cent. on amount of estimate would be a fair charge in such cases.

The death is announced of Herr Moller, one of the leading members of the Berlin Architects' Association. Prior to the year 1868 he had held many important appointments under Government. In that year he was named director of the Royal Porcelain Factory. This post enabled him to display his architectural talent in the reconstruction of the building, and in the many improvements which followed. He was, apart from his professional career, a lover of art. His death (at the age of fifty-five) is all the more lamented by his friends from the fact of his having arranged to retire at the end of this year to enjoy a well-earned repose.

On August 28th the foundation-stone of an allegorical monument to the Knight of the Swan was laid at Cleves. A procession of historical personages took place, and the proceedings terminated with a ball.

The works at the Exhibition building, Hamburg, seem to have been unfortunate in the number of fatal accidents which have occurred there. A workman was killed a few days ago by falling from a height, this being the fifth death which has taken place from casualty during the construction. There are also at present five bad cases of injury in the hospital from the same quarter.

The Imperial Building Commission in Berlin has raised the question whether petroleum should not be used in place of gas, for lighting the grounds which it is intended to lay out behind the university, and also for that portion of the Kastanienwäldchen (or chestnut wood), in which it is proposed to make improvements. Some fears had been expressed that gas would have an injurious effect on the trees. The municipal authorities are in favour of gas being used, due precautions being taken to prevent the pipes from leaking.

The Minister of Public Works at Berlin has addressed an energetic circular to the railway companies under his control, pointing out the necessity of making every possible arrangements before the arrival of trains at intermediate stations, in order to save delays and to insure punctuality in their arrival at terminal points. Junctions are very numerous in many parts of Germany, and hence punctuality is doubly necessary for the convenience of the travelling public. In cases of necessity, particularly when the last train at night has been lost at a junction, the forwarding of passengers to some convenient point by special train is recommended.

ABATTOIRS FOR ST. PETERSBURG.

The new slaughterhouse for St. Petersburg, designed by the architect Kitner, will, it is expected, be opened for use next November. The main structure is already finished. The façade, situate in the Zabalkansky Prospect, is 129 sazhen (301 yards) in length, and the area covered by the whole erection is 20,382 square sazhen (110,968 square yards).

In the front plan are five blocks of buildings, of which one will be occupied by shambles or stalls for the sale of entire carcasses, and which will be leased to tradesmen. The remaining blocks will be taken up with the offices, the dwellings of the attendants, the inspector, and two veterinary surgeons, &c. This row of blocks is separated by a moderate-sized court-yard from the abattoirs themselves, which are situate in the back plan, and disposed in rows, with numerous passages for the entrance of cattle. The abattoir for large horned cattle consists of thirty-six separate compartments, each capable of holding twenty oxen. In each of these compartments a small space for the operation of slaughter is railed off with zinc-covered iron. Here there is placed a movable *cadette*, or platform, upon which the animal falls as it is killed, and which then carries the carcass out of the railed space and into the first compartment. Here it is lifted up by means of a special appliance, called a *tigalet*, and disembowelled, and then by a hook and pulley it is raised and suspended upon a movable circle of sufficient dimensions to hold twenty carcasses at a time. This circle, revolving upon circular rails, which depend from the ceiling, bears the carcass to the doors of the abattoir, where it is lowered upon a car. It should be added that the oxen awaiting slaughter are so placed that they are unable to see the operation of killing or the blood. It is proposed to collect the fresh blood as it flows away, in order to extract albumen from it, the right to do so being farmed out. We may mention here that the hot blood is much utilised at the Paris abattoir as baths for weaklings and sufferers from rachitis, &c.; while other invalids take it internally, and, it is said, with great benefit.

The abattoir for calves consists of ten numbers for holding thirty head each, and the scalding pens for swine five numbers, each for 100 head. On the right of the abattoir are constructed reserve sheds for holding about 320 head of oxen, while on the left, and separate from the rest of the edifice, is a shed comprising two pens to hold each twenty head of oxen. These are for diseased animals, which are to be killed and

burned. Here also the examination of any suspected droves is made by the veterinary officers attached to the establishment. All the offal from the abattoirs will flow into a large reservoir of peculiar construction, situated in the farther part of the ground-plan of the building, in the "machine section." From this reservoir the offal is withdrawn by a pumping apparatus, is strained through filters, and thence passes on direct to the sea through tubes laid down for this purpose for a length of 6 versts (3·978 miles). Both the reservoir and the tubes are made of Schmidt's Riga cement. It is proposed to cover the lower portion of the interior walls of the slaughter-house with slate; the substance of the inner walls themselves is the *béton* prepared by Devars, of Moscow. The total cost will be over 70,000*l.*

CONTINENTAL GATHERINGS.

SEVERAL exhibitions are now "in full blast," and in their respective countries appear to meet with satisfactory success. The Electrical Exhibition in Paris has proved completely successful, and its results will unquestionably do much to further the aims which it was the intention of its promoters to encourage. The English press has already supplied to our public much valuable information regarding the exhibition.

Of the Italian Exhibition, held at Milan, scarcely a word is, however, heard on this side of the Alps, notwithstanding its brilliant success, —a success which is encouraging after the Fine-Art Exhibition so recently held at Turin. It is rather, we learn, from an industrial than from an artistic point of view that it has proved a surprise to the Italians,—a surprise from the fact of the activity shown in Italy of branches of industry believed alone to exist and capable of development in other countries. From this point of view a sensible progress has been marked by the Milan Exhibition. The Italian Chambers have instituted an official inquiry on the Exhibition, and from its reports some interesting information is to be gathered. Italy, whose industrial activity has till now been considered, not alone by the world at large but by itself, to bear chiefly on artistic productions, in which old traditions, taste, and æsthetic sentiment have had more to do than the practical,—industries such as that of the silk-weaver, the glass-blower, the mosaic worker, the furniture producer, the wood-inlayer, and such like,—now has shown an ability to compete successfully in the manufacture of those more mechanical contrivances and aids to industry for which, till recently, they had to rely on foreign countries, and chiefly, let it be remarked, on England,—agricultural and other machines, carriage-building, iron and other metal founding,—while a rumour reaches us of a revival of the lost traditions of the brilliant industry of the bronze-caster. Young Italy, and especially Northern Italy,—more distinct in its character from Central, and certainly from Southern, Italy, than even the South and North of America,—is growing apace, and among the nations of Europe is rapidly obtaining its place; but happily for the romancist, the sentimentalist, and the artist, it will be long before the new spirit will be able entirely to drive out from the old peninsula the cherished memory of its Classic traditions.

Of other exhibitions at present being held on the Continent, that now opened at Lille is deserving notice. Devoted particularly to the fine arts, and international in its character, it certainly will not be from want of attractiveness if it do not prove successful. A selection of pictures from the Paris *Salon* forms not the least feature, while England, Belgium, and Germany have all largely contributed, and we learn from a French authority the English section has been particularly noticed as "remarkable." Opened on the 29th ult., by M. Turquet, the French Under-Secretary for the Fine Arts, the Lille Exhibition will not close till the end of October. A visit to the industrious Franco-Flemish town on the frontiers of France and Belgium will well repay the traveller, and a reference to the ever-handy pages of Murray will amply post him up in the curiosities of the town whence came the Lisle thread and the cotton yarn that has so long competed formidably with our English manufactures. For the artist, be he painter, architect, or sculptor, let not special attention be neglected to the more than interesting Wicar Museum, with its priceless artistic treasures, gathered together by an enthusiast in the days when knowledge enabled the collector in his visits to Italy and the Continent to constantly come upon rare and genuine "finds." Among the numerous works of the great masters of the sixteenth century, possessed by the rich collections of Lille, is a treasure particularly interesting to the architectural visitor. A book of sketches, by Michelangelo, containing more than 150 designs, studies from the works of Brunelleschi, Bramante, and architecture of the fourteenth, fifteenth, and sixteenth centuries, and from various Classic works, original compositions, &c. The catalogue of the Wicar Museum, and the tale it tells of the industrious and benevolent old collector, is alone worth the visit to Lille, apart from the pleasant and instructive recollections that every traveller cannot fail to bear away with him from the old town.

Under the somewhat alarming and sensational heading of "Vandalism," our Paris contemporary *L'Art* has, we see, opened for some time past a special column in its pages to note the acts of injury wreaked on those monuments and works of art which it is the duty of all art-lovers to protect. Under this rubric has recently appeared, — alongside of an attack on the "Vandalism" of painting, cockroach colour, we suppose it would by some be called, the façade of St. Philip in Regent-street,—a sad tale of the threatened destruction of one of the old bridges of Venice, the Ponte Panada on the Fondamenta Nuova, to be replaced by an *iron bridge*, the construction of which will, we learn, cost considerably more than 500*l*, a sum which certainly would be more than ample to solidly repair the old structure, one of those characteristic canal bridges which every visitor to Venice will remember, and said by competent authorities to be the last of its kind left in the city. The proposal has met with violent opposition on the part of a number of persons, but to no avail; the Commission which exists in Venice for the preservation of the public monuments of the city has in vain been appealed to by the *Circolo Artistico*. We should have imagined that so soon after the recent agitation against the threatened restoration of St. Mark's, such an incident as this would not have occurred. Happily the new structure will not resemble in importance the "ghastly iron bridge," as Mr. Ruskin has fitly termed it, which crosses the Grand Canal "at its noblest bend," and its hideousness will, to some extent, be hidden from the eyes of the stranger, who must be venturesome indeed who ever pushes his way so far from the neighbourhood of St. Mark's as the Fondamenta Nuova.

The new Post-office in Paris is, from all accounts, progressing with great rapidity. The *Événement* has recently published some interesting details concerning the erection of the Hôtel des Postes. On the side of the new Rue Étienne Marcel the building has reached the first story. The façade on this side is 140 mètres in length, divided into seventeen large bays, and flanked by pavilions; the façade on the Rue de Louvre has only nine bays. In erecting the immense structure much of the work is brought to the spot ready prepared, and placed in its final position by means of steam cranes. On the side of the Rue de Louvre the cellarage will shortly be completed; all the masonry is, in fact, terminated, the iron girders and joists on which the ground floor will rest remain alone now to be posed. In that portion of the new building on the Rue Étienne Marcel, the works are not in so forward a state, and on the Rue Jean Jacques Rousseau side the masonry has not yet been even commenced. However, by the end of October, it is confidently expected that the whole of the foundations will be above ground. As might be imagined, the value of land in the neighbourhood has singularly augmented; some plots selling for hard upon 120*l*. the square yard, others at a mean of some 1,900 francs (76*l*.); one plot, some 60 square yards in area, going at 204,000 francs, or about 135*l*. the square yard.

FULHAM INFIRMARY COMPETITION.

IN this competition twenty-six designs have been sent in at estimates ranging from 20,000*l* to 66,000*l*. At the first view of the drawings, on Tuesday last, by the Guardians, it was proposed and carried that a letter should be written to the President of the Institute of Architects, requesting him to name three architects,—Fellows of the Institute,—from whom the Guardians might select one to advise them.

APPROPRIATION OF WAGES AND OTHER SOURCES OF INCOME.

To Section F. (Economic Science and Statistics) of the British Association Meeting in York, Professor Leone Levi read a draft report drawn up by himself, and submitted to the committee, consisting of Professor Leone Levi, Mr. Stephen Bourne, Mr. Brittain, Dr. Hancock, Professor Jevons, and Mr. F. P. Fellows, for the purpose of inquiring into and reporting on the present appropriation of wages, and other sources of income, and considering how far it is consonant with the economic progress of the people of the United Kingdom. If it were possible, stated the report, to ascertain with any approach to accuracy the present appropriation of wages and other income of the people of the United Kingdom, it would certainly be of the greatest utility, as it would afford a valuable aid in the consideration of some of those great problems which meet us on every side in our social economy. There are, in truth, no means for ascertaining either the absolute income or the true expenditure of the entire population, and any calculation of the same must, more or less, partake of the nature of an estimate. It is the beauty and glory of what is termed the statistical method that it enables us to calculate the seemingly incalculable. With this instrument at hand, and with a good grip of the teaching of common experience, that which appears but a dream or guess to the uninitiated, becomes to the mathematician and statistician a simple, natural, and reliable result. Many attempts have been made to estimate the total income of the nation of late years. Mr. Gladstone, in one of his addresses, estimated it at 1,000,000,000*l*. The late Mr. Dudley Baxter, in his work on National Income, gave it at 813,000,000*l*. The writer made an estimate of the wages and earnings of the working classes in money or its equivalent, and found them to amount to 418,000,000*l*., and Mr. Giffen, in a paper read before the Statistical Society, estimated the recent accumulations of capital in the United Kingdom at the rate of 240,000,000*l*. per annum. After referring to the personal expenditure and the national expenditure for food and drink, dress, house, coal, gas, water, tobacco, education, literature, science and art, newspapers, church, theatres and music halls, other amusements, taxes, cost of distribution, as 878,000,000*l*. and 684,700 000*l*., he said these two sums give an average expenditure per day per head of 16·63d. as the personal, and 12·71d. as the real or national expenditure, or 25*l*. per annum in the one case, and 19*l*. in the other. Comparing these amounts with the personal and national income the results are as follow: — Income, 915,000,000*l*.; expenditure, 685,000,000*l*.; excess, 230,000,000*l*. The expenditure of the people might be classified into expenditure abroad and expenditure at home, expenditure in materials and expenditure in wages. Without attempting any further analysis, and having regard to the facts above stated, in connexion especially with what has been recently brought out by the census, of a continuously increasing population,—the effect of an increasing birth-rate and a decreasing death-rate,—we may conclude that the present appropriation of wages and other income cannot be said to be opposed to the economic progress of the people of the United Kingdom. A minute examination of the different items of expenditure is, indeed, calculated to remove the impression of any great extravagance on the part of the people as a whole. A large expenditure in bread, meat, woollen goods, and house-rent is a most economical expenditure. An expenditure of 124,000,000*l*. on alcoholic drinks is certainly very large, but reduced to the real expenditure the sum total is 42,000,000*l*. There is one element, however, which does not appear from this calculation, which might prove most unsatisfactory if properly inquired into, and it is that the averages arrived at are, in many cases, the mean of two extremes,—the extreme of waste and the extreme of penury; for side by side with those living in luxury and having no thought of waste, there are large numbers whose conditions of nourishment, state of dwelling-houses and clothing are of the lowest character. Nothing is gained by exagg-rated statements of the national loss arising from the wasteful consumption of this or that article, or by taking as a national loss that which is in effect nothing more than the transfer of money from one to another; but a proper regard to the right expenditure of money is of the highest importance

to the individual and to the nation, for waste and profligacy are the parents of pauperism, demoralisation, and declension. And no greater service can be rendered by the economist or philanthropist than by exhibiting the duty and importance of husbanding aright our resources, and making them conducive to the economic progress of the nation. The committee is fully aware that some of the deductions and reasonings in this report are not founded upon well-ascertained facts, nevertheless it deemed it useful to present them as materials for consideration, and as helps to the elucidation of a subject of the highest social and economic importance. The report points out many wants and desiderata, and the committee recommends the reappointment of a committee, consisting of a larger number of members, for the purpose of suggesting means for supplying the same on a uniform and scientific basis.

SUGGESTED REMEDIES FOR WAGES DISPUTES.

THE Rev. W. H. Jemison, LL.B., Vicar of Stillington, York, read the following paper before the Economic Science and Statistics Section of the British Association on "Remedies proposed for Wages Disputes": — The prevalence of disputes about wages, and the serious character of their consequences, have naturally made thoughtful persons anxious in pursuit of remedies whereby these disputes may be composed or prevented. A few of the best known and most effective of the remedies proposed are here considered. The first to be mentioned is the plan of arbitration, on which employers and workpeople refer the matter in dispute to one or more persons in whose judgment and impartiality they have confidence. Taking such a step is wise, and often productive of good results, but arbitration is at best a rough expedient. The value of labour, as of other things, cannot be correctly determined prior to experience, it being the actual result of several agencies. The arbitrator's decision is, in fact, only an approximation to the exact truth, which, in the absence of something better, it is prudent to accept. Again, the plan is strictly applicable only within certain limits. It may reasonably be declined where the parties are under no need or obligation with regard to each other, or where the principle of an engagement and all the facts of the case are already known. Neither employers nor employed are to be held bound to leave it to an umpire to say whether or not they are to agree to terms, which, in their opinion, would expose them to uncalled-for loss, nor whether stipulations of undoubted right are to be carried into effect. The former is a matter for free choice, and the latter for legal compulsion. These exceptions, however, leave a large mass of cases in which reference to an arbitrator is most natural and reasonable, and in every way better than continuing a dispute. In such cases the reference should be prompt, in order that the work of production may not be checked, and the work of loss begin. Even though the rate of wage arrived at by the arbitrator may not be the perfectly correct one, and his decision be rather a cutting of the knot than an untying of it, it is far wiser for the parties to agree to abide by such decision than to keep the dispute open. It is better to refer to arbitration even more cases than strictly belong to it than incur the likely consequences of dissension. Important as it is to settle disputes which have arisen, it is still more so to prevent their occurring. Boards of conciliation, which have been formed for this purpose, are really arbitration under a more settled form. These boards, which have been established in some trades, and have for a long time existed in France, consist of an equal number of representatives of employers and employed, who discuss among themselves the circumstances of the trade, and decide on what is best for the interests of the parties. Such boards are well calculated to promote a good understanding, and the maintenance of peace and industry. No doubt, in their operation, there is something like cutting the knot instead of nicely and perfectly untying it, but there seems no reason why the plan should not work with the best results. It only needs that the representatives on both sides be wisely chosen; that they deliberate with calmness and moderation; and that their decisions and counsels be loyally accepted by those for whom they act. It is sometimes found desirable for these boards to agree upon a sliding scale, according to which wages rise or fall with the selling price of the goods produced and the circumstances of the trade. The adoption of such an expedient diminishes the appearance of anything of a merely arbitrary or fitful character in the action of the boards, and makes wages become in a manner self-regulating. There must, however, be a proper rate of wage fixed on to start from, and a proper price of goods taken as the standard, and all the necessary conditions made clear. Though, even so, the best adjusted scale will occasionally need to be revised and recast. In these Boards of Conciliation, fairly and efficiently carried out, we have a valuable method of diminishing the number and acerbity of disputes about wages. Another method proposed for the prevention of these disputes is the adoption of the system of co-operation. This method attracts considerable attention, and has much to recommend it. It is claimed in its behalf, that though not really at work for much more than twenty years, it has already something like one-twentieth of the population associated on its principles. Under this system an attempt is made, not so much to adjust as to extinguish the opposing claims of employers and employed, by getting rid of the distinction between these two classes. To use the recent words of a noble expounder (Lord Derby) of the system, "It is like the settlement of an old family law-suit by the marriage of the litigants." A number of workpeople put their savings together or borrow capital; they procure the buildings, machinery, and materials necessary for carrying on a business; and they work together, each doing what he seems best fitted for and receiving wages for what he does. The co-operators are thus wholly or in part their own labourers and their own employers; and at certain periods they divide amongst themselves as gain the whole or part of whatever remains over after defraying necessary expenses. A distribution of results thus takes the place of a partition between wages and profit. By such means, it is claimed by the advocates of this co-operation movement, the occasion of the disputes so common under the old system is necessarily removed. It is hoped, too, that a higher tone may be introduced by it into business relations: work and labour rendered more honest through the general interest of all parties in the result; and indebtedness discouraged through the practice of dealing for ready money rather than on credit. The co-operative system tends also to educate the operative classes in principles of self-reliance and honest labour, and in an acquaintance with the difficulties which have to be encountered in the management of business. These various good tendencies entitle the movement to favourable consideration, and to any fair opportunity of developing itself and proving its fitness for general adoption. I contend, however, that that fitness is not yet proved. The plan of co-operation, though so available and beneficial under some circumstances, does not seem equally so under others. It may succeed, for instance, in cases where the several co-operators contribute equally to the results produced; or where the management of the business is comparatively simple, the sunk capital small, and the returns pretty regular. But in businesses which are different as to these several particulars, the general adoption and success of the system will be more unlikely. When, for instance, the workpeople contribute different kinds and quantities of labour or other aid, a difficulty must be likely to arise about apportioning to them their respective shares of remuneration. To make a really just and satisfactory apportionment would require a more general and accurate knowledge of the several elements of value,—both of labour and goods,—than any man can have before actual experience. Again, as to business management, it is no disparagement of the operative classes to say that they cannot be expected to have the qualities necessary for the management and direction of a large business,—qualities which are almost invariably the result of special training and experience. Of course these qualities might be hired at a commensurate remuneration, but there will still be a disadvantage in their exercise when compared with that in the case of an individual or firm ever on the look out for favourable opportunities, vigilant, enterprising, and speculative. There are obvious difficulties, too, in the way of members of the operative classes, or those only immediately above them, saving or borrowing sufficient sums to form the sunk capital of an enterprise of great extent; and also in their inability to bear the far-reaching consequences of a failure. The system seems to presuppose more extensive knowledge, more acquired mental power, and more self-control than the operative classes in any country can be expected to possess. It has often been observed that the co-operative principles succeed better in the business of distribution than in that of production; and the explanation of the diffesence is in what I have stated. Lord Derby, in opening the recent Co-operation Congress at Leeds, very fairly acknowledged the difficulty in the way of co-operation as applied to farming. He said, "The question arises,—have you got the men? Men accustomed to work,—willing to put themselves under orders, though they are their own masters, and intelligent enough not to be disheartened, and throw up the game if they are not lucky at the outset. If you can find men of that sort the experiment will probably answer; if you cannot it had better not be tried." These words must commend themselves to every one's good sense; but the difficulty which Lord Derby sees in the case of farming, together with other difficulties, is, I think, to be feared more or less in other branches of industry as well. Again, as there are many lawsuits which cannot possibly be settled "by the marriage of the litigants," so there are many social interests which may not really conflict, but they cannot possibly be amalgamated. To see what I refer to I would only ask the Section to reflect on the vast mass of productive interests at the present moment which are the result of that individual effort, for which no adequate place is found in the system of co-operation. Look at our great capitalists, our great business-managers, our industrial chiefs, who, by the dint of individual and personal fitness, take and hold their position of eminence in manufacturing and commercial life. I ask what place is there for such in the system of industrial co-operation? Or is it supposed that the rise of such chiefs will cease? I trust that we have no hopes of any such dead level. Combined effort, indeed, has its great field of achievement, as exhibited in our railways and various joint-stock undertaking; but it is only under certain conditions and within certain limits that it is superior to or even equal to individual effort; and even where combined effort is most successful, how often is its inception really the triumph of individual genius and perseverance. Again, there is a certainty, at all events, that the practice of accumulation will not be carried out by all persons in the same degree; for all have not the same will and ability. There will, therefore, be here and there among men various amounts of wealth, and the owners will often be persons who will prefer to employ their capital themselves independently, to throwing it into a common concern. In such cases, at least, the old distinction between employers and employed will necessarily survive. On the whole, then, it seems to me that although the co-operative system has much to recommend it, and if it were only for the high aims of many of its promoters, it ought to receive favourable consideration as an attempted solution of the wages-difficulty, yet that it is far from being universally applicable; and that we should be careful before we make up our minds to regard it as the ultimate form of industrial life. Another system, to which, in the last place, I shall refer, which has been proposed, and to some extent put in practice, for securing harmonious relations between employers and workpeople, is that known as the system of industrial partnership, or participation in profits. Under this system the workpeople are paid a certain wage, adjusted as nearly as possible to the condition of the labour-market, and there is given in addition a further sum proportioned to the success of business and the degree in which they have severally contributed to it. Instead, however, of considering this addition as a share of profits, it will be better to regard it as an increase of wage on account of more efficient labour; for nothing can conveniently be termed profit but the employer's share. This system, though not without its difficulties, has very considerable advantages to recommend it. It is favourable to production, for under it every workman has a direct stimulus to increased and careful exertion; it tends beneficially to the development in him of whatever may be his peculiar talents, and to the strengthening of the principles of emulation, self-reliance, and self-respect; his interest being so closely connected with his own character and conduct; and it also tends to conserve and pro-

mote good feeling between employers and employed, all having more or less an obvious and common and real interest in the success of the business. Besides, under this system, the direction of the business is left in the hands of those most competent to conduct it; the cost of production is lessened by the diminished need for superintendence; and, lastly, in the case of failure, an intolerable burden does not fall on the humbler workers, their loss being limited to an interruption of employment. The plan, as I have said, no doubt has its difficulties; difficulties as to the ascertaining of the fixed wage to be started from or adhered to; and the working of an efficient check and rule for measuring the claim of each workman to additional pay. In adjusting such claims regard must properly be had to the nature and circumstances of the business, including the amount and duration of the employer's outlay, some parts of which are of a stated character, as the amount of fixed capital which he had to provide, and others, as the cost of raw materials, varying from time to time. Account, in short, must be taken not so much of the general success, as of that portion of it which is due to the efficiency and diligence of the workpeople. The adoption, however, of a sliding scale, under which the increase of pay bore some constant relation to variations in the selling price of the goods produced, would perhaps be fair and satisfactory; for, in estimating the value of labour, we can scarcely disregard the value of its product. The several difficulties to which I have alluded will no doubt require attention; but they are, I feel, such as may be overcome in practice, and I believe are considerably overcome where the system is fairly in operation. Of course, under this system, should any question arise either as to the stated wage or the apportionment of extra pay, it can most properly and wisely be referred to arbitration. In expressing, for my own part, a decided preference for this system as the most hopeful, which preserves the natural distinction between employers and employed, leaving to the former the direction and management, and securing to the latter an interest in the results, I still would not be understood as desiring in the least to detract from the claims of any others. Various systems such as I have named will each and all find fields for development in our social life; and in so far as they have capabilities and fitness should all be encouraged by being allowed fair play. Natural powers and laws will work out their own results, and prove the best system paramount; but it is as difficult for us to predict and define the future form of social relations as to know the precise shape of the tree which is yet to spring from the acorn. What is especially to be desired in these matters is the prevalence of full and free competition, both for systems and individuals; human law taking care that none violate the rights of another; and moral and divine law being so honoured and influential that no persons will have the wish to do so.

Mr. Jeremiah Head, of the firm of Fox, Head, & Co., ironworkers, Middlesbrough, said he had some experience with regard to the question before them. About eighteen years ago some other gentlemen and himself established those works. After two years they found that they lost about a quarter of their total time in strikes, and in a fit of desperation they adopted a scheme, which had been advocated rather strongly by the author of the paper, called "industrial partnership." They adopted it for three years as an experiment, and as nothing particular occurred to induce them to make any change, they continued the system for other five years, and having experienced good times, it being from 1870 to 1874, they were enabled to distribute in the shape of a dividend to their workmen some 6,000*l*. He was sorry to say that at the end of five years they found that it was not to their interest to carry it on any longer. Many of their men became connected with trade-unionism, and as the unionists were adverse to the system that had been so successfully in operation, it came to an end, and there was now a Board of Arbitration and Conciliation, where the men and the masters are equally represented, and matters relating to their interests discussed and settled. It was, in other words, a place where a method of haggling went on, and the real thing that apparently regulated it was the state of trade at the time. He was satisfied, after much attention to the subject, that industrial partnership or industrial co-operation would never be successfully carried on, the men being unfitted for the commercial portion of the business to make it a success; but co-operation, in the form of co-operative stores, where they were their own customers, and were not obliged to seek customers in distant parts, was a system that had been successfully tried, and he could recommend it to the working population.

THE FORMATION OF COAL.

MR. EDWARD WETHERED, F.G.S., F.C.S., read a paper on the above-named subject, before the Geological Section of the British Association last week. The author first reviewed the researches of Hutten, Göeppert, MacCulloch, Sir James Hall, Sir W. Logan, and Dr. Dawson, and then summed up the conclusions now entertained as to the formation of coal, as follows:—1st. That the beds of fireclay which underlie all seams of coal, represent the original land-surfaces upon which the coal-forming vegetation grew. 2nd. That the stigmaria found in the underclays were the roots of that vegetation, which implies that the plants were of the Lepidodendroid order. 3rd. That the vegetation grew near the mouths of great rivers, in swampy ground, and there underwent submergence; changes then took place which converted the vegetable matter into coal. 4th. That the change of coal from one variety to another, even in the same seam, is the result of metamorphism, and is indirectly caused by the contortion of the surrounding strata, whereby facilities for the escape of gases evolved by the vegetable decomposition have been produced. The author's exceptions to the above were,—1st. That coal was not formed from vegetation of the Lepidodendroid type, and that therefore the stigmaria found in the underclays are not the roots of the vegetation which gave rise to the coal, unless it was from the spores of such plants, which the author considered wanting in proof, though seams of coal did undoubtedly contain spores. 2nd. That the varieties of coal and the change which sometimes takes place in one and the same seam are not due to metamorphism, nor are they dependent upon the contorted state of the surrounding strata, but arise from the greater or less chemical decomposition of the vegetable mass, influenced by the circumstances under which it was submerged. The reasons which had led up to these conclusions were:—1st. That we have proof of other vegetation during the coal-period besides the Lepidodendroids, but their roots have not been preserved, owing to their being of a more perishable nature than the stigmaria. 2nd. Beds of underclay are frequently met with full of stigmaria, but are not followed by seams of coal. 3rd. Coal must have been formed from a compact mass of vegetation, such as could not have been produced by large trees (as the Lepidodendroids were) growing *in situ*. The uniform thickness and comparative freedom from inorganic contamination would demand a mass of vegetation into which only a limited amount of sediment could penetrate. 4th. The finding of a fossil-tree standing *in situ*, upon which so much stress had been laid by some authors, is a rarity. Though the author had spent much time underground in collieries, and seen hundreds of fossil trees drifted into the position in which they have been found, he had only twice seen instances of them standing where they have grown. 5th. If seams of coal were formed from Lepidodendroid trees the tough base layer would be easily detected, which has never been the case in any true bed of coal. 6th. If the stigmaria found in the underclays represent the roots of the coal-forming vegetation, we should expect to find the fructifications immediately over the coal, which is not the case; with the exception of cordaites (which, in the author's opinion, was a reed), remains of fossil flora are not found for the first 2 ft. or so over the coal. After a careful investigation underground of the conditions under which coal was formed, the author has arrived at the following conclusions:—On the land grew the vegetation of the period, represented by lepidodendrons, sigillaria, calamites, &c. As the land sank and the waters encroached, the land vegetation gradually disappeared, but the roots remained in many cases, and those which offered the great resistance to decay are the ones preserved in a fossil state, hence the occurrence of stigmaria. As the waters advanced, the ground would become swampy, and then we might expect to see spring up reeds, mosses, and other vegetation suitable to the changed condition. It is to vegetation of this kind that the author ascribes the formation of coal. Reference was then made to the Presidential address of Professor Ramsey to the British Association in 1880, in which the recurrence of the same kind of incident through geological time was advocated. The author then asked, why the coal formations of the carboniferous period should be an exception, seeing that the modern lignites and deposits of peat were instances of coal in the progress of formation. It was then pointed out that these deposits were not composed of large trees, but of a lower order of plants. Coming to the varieties of coal and the change which sometimes takes place in this respect in one and the same seam, it was shown that the difference between bituminous and anthracite coal was that the latter contained a greater proportion of carbon and a less amount of volatile matter than the former. It was then contended that if the decomposition of the coal-forming vegetation took place without being affected, to any extent, by minerals capable of oxidising the carbon, a coal would be formed having a large proportion of carbon with a less proportion of volatile matter than is found in bituminous coal. The author explained this by briefly reviewing the process by which vegetable matter has been converted into coal. It chiefly depended upon the amount of oxygen which could unite with the carbon for carbonic acid, and the amount of hydrogen which could unite with the carbon to form marsh gas. By this process oxygen and hydrogen would pass off in greater proportion than the carbon, thus increasing the proportion of the latter to the whole. If, however, the submerging waters placed in contact with the vegetable mass substances capable of supplying oxygen to the carbon, then there would be a decrease in the proportion of the latter, and what the author termed "fixed oxygen and hydrogen" would increase in proportion to the whole, and give rise to a coal of a bituminous nature. With a view of ascertaining whether the chemical composition of the beds overlying a seam of coal which has changed from bituminous to anthracite also changed, the Welsh "9-ft." seam was selected, which, near Cardiff, is semi-bituminous, and at Aberdare becomes anthracitic. Specimens of the overlying strata were selected from the two districts at each foot above the coal for 5 ft.; these were analysed, and it was found that the beds from near Cardiff were considerably more argillaceous, and, as a whole, less ferruginous than those at Aberdare. It would be rash to attempt to determine the exact chemical nature of the sediment deposited over the coal-forming vegetation in the two localities, as, with the exception of silicate of alumina, the silicates and other minerals would have undergone decomposition at the expense of the carbonic acid given off from the coal-forming vegetation. There was, however, a decided change in the beds of the two sections presented, which could not be ascribed to metamorphism. It rather appeared to point to the sediment containing different constituents, which must have a very considerable effect on the vegetable mass. It was to this that the author was inclined to assign the change in the character of the coal.

A NEW FORM OF LIGHTNING CONDUCTOR.

BEFORE the British Association meeting at York, last week, a paper by Mr. Samuel Vyle, Associate of the Society of Telegraph Engineers, "On a new Form of Lightning Conductor," was taken as read, he being absent, with Mr. W. H. Preece, F.R.S.; Professor Adams, F.R.S.; Professor Symons, F.R.S., and other gentlemen interested in the subject, testing the lightning conductors on the Minster. The paper referred to the damage caused by recent thunderstorms, and pointed out that experience and the opinion of scientific authorities went to show that a lightning-conductor of sufficient capacity, when properly fixed, and having good contact with the earth, was a certain protection against lightning. The radius protected by each conductor was still a matter of controversy, but it appeared that a conic section equal to its height was within the bounds of safety. Referring to the repeated utterances of scientists as to the absolute necessity of testing lightning-conductors, in order to know their condition, the author indicated the difficulties that existed in getting these tests made, which were both costly and dangerous, a wire from the ground to the top of the conductor being necessary before the elec-

trician could commence; on lofty places and high spires this was conspicuous. Recognising this difficulty, last year Mr. Vyle was led to the invention of the new form of conductor which he exhibited. It was, in fact, a copper cable, with an insulated wire set within the core, which, being metallically connected to the conductor at the top, offered a ready means of testing it whenever desirable, the lower end of the inner wire being always within reach. Having, then, this testing-wire, it became necessary to provide the means of measuring its resistance, and this has been done by a differential galvanometer, fitted with three keys. The depression of two of them separately sends currents up the testing-wire to the top of the conductor, down which it passes to the earth, and also through an artificial circuit of resistance exactly equal to that of the wire and cable referred to. The indicating-needle is deflected to the side of the key depressed. If, however, both keys are pressed down at the same time, the needle will remain stationary or balanced, thereby proving the conductor good. In case the needle is deflected the third key is brought into use, and being depressed at the same time as the first proves whether the conductor is good, or the fault to be looked for above ground.

VISITS AND EXCURSIONS BY THE BRITISH ASSOCIATION.

THE Jubilee meeting of the British Association in York appears, as we have already said, to have been a very successful gathering. We have given reports and summaries of some of the addresses and papers read in the sectional meetings, but, besides the instruction provided for members and visitors indoors, visits to manufactories and public works, and excursions to places of antiquarian interest and natural beauty or picturesqueness, were organised in great number. We append a few notes of these visits.

York Gas Works.—At the York Gas Works, Monkgate, visitors were conducted by Mr. Charles Sellers, secretary, who explained the whole process of gas manufacture, and said his company used the same kind of Durham coal as was chiefly used by the London companies. They used lime exclusively for purification. The old lime is sold to agriculturists, it being an excellent fertiliser. The coke-breaking machine attracted considerable attention. By it coke is broken and screened, and made suitable for domestic purposes. It may be stated that York was first lighted by gas in 1823, and the present gas company was amongst the first in the country to sell gas at so cheap a rate as 2s. 6d. per 1,000 ft.

The Buckingham Works.—These works, the factory of Messrs. T. Cooke & Sons, the well-known astronomical and mathematical instrument makers, were also visited. The premises stand on Bishophill, on the site of the palace formerly belonging to the Dukes of Buckingham. These works were built twenty-five years ago by Thomas Cooke, originally a schoolmaster, whose mathematical talent earned him a wide reputation among men of science; and his memoir written by Colonel Strange for the Royal Astronomical Society of Great Britain is a fitting tribute to his genius. He died in November, 1868. A great portion of Messrs. Cooke's work is done for use abroad, instruments from these works having been used for the Indian Government Ordnance Survey, for measuring the Pyramids, and for many scientific experiments in other latitudes.

Central Saw Mill.—Apart from the work which is carried on in the Central Saw Mill, Newgate, the building itself is of some interest. It was erected on the ruins of a house of the same name. Previously to its destruction by fire, about seventeen years ago, the upper part of the building was of timber. The walls of the lower part mostly remain. The building is stated to have been of the fourteenth century, and had at the end, where the present doors are, an original archway, and there were two curious windows, one of which is yet to be seen. It has by some been thought to have been a prison for offenders within the precincts of the court, while others have held that it was a chapel. The "Vicars Choral," however, "had a house, said to stand over against the churchyard of St. Sampson, where they antiently lived to go there and kept hospitality in their common hall." But to whatever purposes or uses in ancient times this building has been devoted, it has for the past thirty years been in the occupation of Messrs. Charles Ernest & Co., who have carried on the manufacture of every description of drawer and door knobs or handles, also croquet, tennis, racquets, cricket bats, &c. The business of general turnery is carried on in these premises, and some of the machinery is interesting.

Ebor Works.—At the Ebor Works of Messrs. Varvill & Sons, North-street, the manufacture is extensively carried on of planes of every description for joiners, shipwrights, coach-builders, &c.; also all kinds of tool handles. The principal kinds of wood used are beech, box, ebony, and sycamore, all of which is bought in the round timber, sawn up, then steamed for twenty-four hours, after which it is cut up into stocks, and laid away for two years to season. Then it is worked up into tools. This firm also make plane irons of all sorts, and most of the processes may be seen in operation.

York New Waterworks.—Considerable improvements have lately been made at these works. It seems that in the year 1682, during the reign of Charles II., waterworks were first established in the Lendal Tower, adjoining Lendal Bridge. A pumping-engine, worked by two horses, was placed in the tower, by means of which a scanty supply of water was furnished to the citizens every week. The mains at that time were the trunks of trees hollowed out and fastened together, and laid down in the streets. This primitive state of things went on for nearly a century, when the works were purchased by Colonel Thornton, who made considerable improvements in the service of water. At his death the property came into the possession of his son, also a colonel, when a steam-engine was introduced, the building enlarged, and hot and cold water baths were provided in a house adjoining the tower, and these baths are still in existence. Colonel Thornton, in 1799, sold the waterworks, and the purchase-money was provided for by the issue of eighteen shares. The new proprietary effected other improvements. They raised the height of the tower, and made it 58 ft. 6 in. above the summer level of the river. The steam-engine was of eighteen horse-power, raised 16 gallons of water per stroke, the number of strokes being eighteen every minute. The water thus pumped was at the rate of 17,280 gallons per hour, or 207,360 per day of twelve hours. An extra pipe was placed to convey any surplus water into a tank beneath the tower, the floor of which was about 7 ft. below the bed of the river. At the beginning of the present century the population of York was rapidly increasing, and houses were multiplying in all directions in the suburbs, rendering it impossible for the company to overcome the difficulties with which they were beset, owing to the limited character of the resources at their command. A new company was accordingly formed in the year 1846, and the works of the old company were purchased under the authority of an Act of Parliament, which authorised the creation of a capital of 60,000*l.*, with borrowing powers to the extent of 20,000*l.* on mortgage. The new company secured a suitable site at Acomb Landing, adjoining the river, a few hundred yards higher up than Clifton Scope, and upon the spot was erected a commodious building, in which were placed two powerful steam-engines for the pumping of water from the river. Outside the building were provided two subsiding reservoirs and three filter-beds, as well as tanks, conduits, pipes, and other apparatus for raising the water from the river, and afterwards lifting it to the high service reservoir on Severus Hill, to be thence distributed through the city. The two steam-engines are each capable of working to about sixty horse-power. The filter-beds are constructed on a similar principle to those which were first suggested and put in operation by Mr. Simpson, at the Chelsea Water Works in 1828. Three of the filter-beds are 60 yards by 20 yards each, and one circular. The depth of the beds is 6 ft. from the face of the sand, and 5 ft. below for the filtering medium, which consists of 2 ft. 6 in. of fine river sand for the top layer, and the same depth of various sizes of gravel for the lower layer. Three of the beds are generally in use at one and the same time. About 62,500 gallons of water are filtered every hour. In 1876 such was the increased consumption and demand for water that the company obtained an Act of Parliament to extend their works, and new capital was created for the purpose. Recently a new engine-house, 42 ft. long, 21 ft. broad, and about 40 ft. high from the floor to the roof, has been erected, and also a boiler-house in connexion therewith, in the Tudor style, with a chimney 115 ft. high. It is supported at the base by buttresses at each angle, and the upper portion is octagonal in shape, and terminates with a battlemented coping. The whole of these buildings are of brick with stone dressings. In the new engine-house have been erected two powerful engines of 40-horse power each, and both are provided with a filter water-pump, and also a river water-pump, capable of raising from the river each 931,600 gallons per day of twelve hours, and sending the same amount of filtered water daily into the service reservoir on Severus-hill for the supply of the city. The two engines combined are therefore able to send 1,863,200 gallons of water per day for the use of the citizens, and this immense amount of water we understand could without any difficulty, in case of necessity, be increased to 2,000,000 gallons per diem. In addition to this, the old engines, which have done their work well so long, are still employed. In the new boiler-house have been erected four boilers, provided with smoke-burners.

York Glass Works.—The York Glass Works, Fishergate, are the oldest and most important in the district: medical bottles are the chief speciality, and these are shipped all over the world. The manufacture of bottles and other vessels of glass was not introduced into this country till 1557, and it did not make much progress till 1690, in the reign of William III. The art of glass-making was early practised in York. Drake, the historian of York, says that a "glass-house" was first erected in a lane near Margate; that the manufacture was continued for some time, but at length discontinued,—probably about the close of the seventeenth century. A local halfpenny was some years ago found, bearing the inscription "York Glass Manufactory." Part of the works of the York Glass Company, Limited, were erected in 1794. The business, although on a small scale, was a prosperous one; but it was not until 1864 that the present company was formed. The works have since then been considerably enlarged. Several warehouses and workshops have been built, and the furnaces altered and adapted to more modern principles and the latest improvements in glass manufacture. The works (according to the *York Herald*, from which journal we cull some of our particulars) are built on the site of the ancient priory of St. Andrews, Fishergate. The abbey was situated between Blue Bridge-lane and the present works, and the river Foss, and the high-road to Fulford. A portion of the Priory walls may still be seen in the boundary-wall in Blue Bridge-lane. The abbey or priory of St. Andrew was founded in 1202, by Hugh Murdoc, archbishop of York.

Railway Carriage Works.—A party of gentlemen were conducted over the carriage and wagon shops of the North-Eastern Railway Company by Mr. Elliot, the superintendent of the carriage department. The visitors were first conducted through the framing department, and were shown the machinery for mortising, tenoning, boring, &c., the several parts, all which machines, as may well be understood, are constructed with a view to the greatest possible economy of labour. The great strength of the framework of the under-carriages was a matter of curiosity and interest. A powerful mortising machine, by Messrs. Powis James, Western, & Co., of Lambeth, was the subject of a good deal of interest, on account of its great power and precision in cutting with easy application. The body and trimming and painting departments were next inspected, and this being done, the construction of the solid wheels was explained, and it was stated that a composite carriage was generally estimated to last about thirty years, the cost of construction being 400*l.* The smiths' shops next came under notice, and looked even more busy and animated than the carriage shops. The departments allotted to the manufacture of the company's lurreys, as well as the wagons for various descriptions of traffic, were shown in succession, and it was explained that the force employed were able to construct something like 100 wagons a week, and that 30,000 had been built during the last ten years. After a rapid inspection of the "hospitals," or repairing shops for carriages and wagons, the party were much interested by an inspection of the Westinghouse brake, an engine and carriage being coupled and put in motion to show its operation. The explanation, with a dissecting of the parts of the valves, &c., was a matter of considerable interest, and afforded a good deal of satisfaction to the visitors. After this Mr. Elliot conducted the party through the extensive

sheds for storing and drying the timber used in the construction of the various kinds of vehicles.

North-Eastern Railway Locomotive Works.—The Locomotive Department of the North-Eastern Railway was also visited, by permission of Mr. Stephenson, the superintendent. The department, which occupies a block of buildings at the end of Queen-street, near the old station, employs between 300 and 400 men, and though devoted chiefly to the repairing of locomotives, is provided with plant sufficient for their manufacture. The first place entered was the boiler-shop. The fitting-shops were next shown. After a survey of the varied work done here, the machine-shop, with its numerous and intricate machines for drilling, planing, cylinder-boring, &c., occupied considerable attention. The pattern-shop having been visited, the arrangement for fixing the tires of wheels was next examined. The smiths' shops were next viewed, and then the new buildings for fitting and erecting engines were arrived at. Thence the party proceeded to the goods warehouses in Leeman-road. Here a great saving of horse-flesh was noticed in the extensive use of hydraulic power. The large new engine-sheds were the last portions of the works visited. These sheds have standing-room for about sixty locomotives, a flue being placed over each stand, thus keeping the building clear of smoke.

Excursions.—On the 3rd inst. there was an excursion to Castle Howard, the seat of Mr. George Howard, M.P. Here the valuable collection of paintings and other works of art was inspected. The design of Castle Howard was by Sir John Vanbrugh, afterwards the architect of Blenheim House, Oxfordshire. The south front is 323 ft. in length, and consists of a centre and two wings. The centre has a pediment and entablature supported by fluted Corinthian pilasters, and is approached by a broad flight of steps. The north front has also a centre of the Coristhian order, with a cupola surmounting it, and two wings, the west one being the design of Sir James Robinson, and differing in style from that on the east. Helmsley, Duncombe Park, and Rievaulx Abbey were also visited on the same day. Permission had been obtained to drive through Duncombe Park, which is well belted by trees and stocked with deer and shorthorns, and from which most extensive and varied views of the country can be obtained. As the ruins of the Hall were inspected, there was a general feeling of regret that so fine a building with its art treasures should have fallen a prey to the disastrous fire which occurred three years ago. This structure was in the Doric style of architecture, and was the design of Sir John Vanbrugh. The rebuilding of it will shortly be recommenced. Rievaulx Abbey was described by the Rev. C. N. Gray, vicar of Helmsley. There were also excursions to Scarborough, Harrogate, Brimham Rocks, and other places of interest. In spite of the very wet weather, which mostly prevailed, each of the excursions attracted two or three hundred ladies and gentlemen, who, from the published accounts, seem to have successfully emulated Mark Tapley in being jolly under difficulties.

THE SOUTH HORNSEY LOCAL BOARD'S NEW OFFICES.

THERE are few suburban localities around London which are increasing at the same rate of progress as the neighbourhood of South Hornsey. The district under the management and control of the South Hornsey Local Board covers a very large area, stretching something like two miles from south to north, and from Stoke Newington to Finsbury Park between east and west. Within this extensive area several hundreds of houses have been erected within the last two or three years, many of them of the villa character, and at the present time building is still going forward in the district on a very large scale.

The continued expansion of the neighbourhood has induced the Local Board to erect new public offices, and the buildings have been in progress during the past three or four months. The site of the offices is in Milton-road, not far from the centre of the Board's district. Although the structure is already considerably advanced, the formal ceremony of laying the memorial-stone has only taken place during the present week, the Chairman of the Board having performed that office on Thursday afternoon, in the presence of the members of the Board, and about 200 invited guests. The building, which is in the modern Classic style of architecture, and in Portland stone, has an elevation to Milton-road 70 ft. in length, and 40 ft. in height, containing the ground-floor and a lofty story above, with dormers in the roof. The ground-floor portion of the elevation has ornamental pilasters with Ionic capitals, the floor above also being faced with similar pilasters and composite capitals. Each floor contains a range of arched windows, those on the story above the ground-floor being eight in number. Above the ground-floor there is a projecting cornice, and the elevation is surmounted by a balustrated parapet. A central porch, 12 ft. wide by 5 ft. deep, with an arched door and gateway, leads into an entrance-hall, 20 ft. by 12 ft., the walls of the entrance-hall having pilasters, and the floor is laid with encaustic tiles. The ground-floor contains, on the right and left of the entrance-hall, the clerk's and the surveyor's offices respectively, together with the inspector's office, the general offices, and strong-room. A staircase, 17 ft. wide, in Portland stone, with an ornamental balustrade, leads to the board-room on the upper floor. This apartment is 43 ft. by 23 ft., and is 17 ft. in height to the ceiling, which is coved and panelled, and has three sun-burners. The walls are enriched by twelve columns. Adjacent to the board-room are two large committee-rooms, together with waiting-rooms and lavatories. A portion of the building is intended to be finished and fitted as the residence of the board's surveyor.

In addition to the new office buildings as above described, a separate building close adjoining is to be erected as the fire-engine station. This building will likewise have its frontage to Milton-road, the elevation being in Portland stone, and though plainer in character, uniform to some extent with the new offices. In addition to the standing space for the fire-engines, the building will contain the fire brigade superintendent's apartments, whilst at the rear will be the stables and yard. The buildings also include a mortuary for the purposes of the district, which will be erected at the east side of the fire brigade stables. The whole of the buildings and grounds when completed will cover an area of 140 ft. in length and 96 ft. in depth.

Mr. E. Fry is the architect of the buildings, and Mr. S. Goodhall, of Stoke Newington, the contractor, Mr. W. R. Smith being foreman of the works. The cost of the buildings will be about 9,000*l.*

THE NEW PEABODY BUILDINGS.

SOME of the largest blocks of buildings which have yet been erected by the Peabody trustees are at present in progress in different parts of the metropolis. One of the most important of the blocks is that which is now being erected on the spacious plot of ground situated between Drury-lane and Great Wild-street. These buildings, which are now far advanced towards completion, consist of thirteen distinct structures in four main blocks, one facing Drury-lane, one in Kemble-street, a third facing Great Wild-street, where will be the principal entrance, and the fourth block stands within the ground. The buildings contain in all 819 rooms, forming 312 tenements of two or more apartments each, in addition to 175 single rooms. The buildings are six stories in height, and, like all the rest of the erections of the trustees, are in white brick. Four blocks, containing 280 rooms, are also nearly ready for occupation in Bedfordbury; whilst fifteen large buildings of a similar character are in course of erection on the Pye-street site. In addition, operations have just been commenced on the Whitecross-street site, and also on the site in Westminster, in the rear of the south side of Victoria-street. The Westminster site is between one and two acres in extent, and the blocks about to be erected upon it will be amongst the most extensive of the buildings belonging to the trustees. Ten blocks, comprising altogether 610 rooms, have been opened during the present year in Glasshouse-street, and the trustees state that before the close of the year they expect to have provided in addition to their tenements already occupied, accommodation for 760 families, or upwards of 3,500 individuals. The average rent of the Peabody Buildings all over London was estimated at the close of last year to be 4*s.* 4½*d.* per week for each dwelling, or at the rate 1*s.* 11½*d.* per room. Messrs. Cubitt & Co. are the contractors for the whole of the several blocks now in course of erection, under the direction of the trustees' architect.

MAIDS MORTON CHURCH.

BUCKINGHAMSHIRE is by no means a rich county for the ecclesiologist, and it is somewhat singular that in such a purely agricultural district the towns should be so remarkably uninteresting, and the churches should have fared so badly. Yet, somehow or other, the important towns in Buckinghamshire seem to have been deprived of their ancient churches about a century or so back, and for what reason it is impossible to say. Buckingham has lost its ancient church, and in its place we find a strange building, consisting of a Batty Langley tower and spire, a slice of a "Georgian" nave, and the residue Revived Gothic. At Stony Stratford we find a solitary old tower and a Brummagem Gothic church, which we have been told is to be rebuilt. It is true Stewkeley, Hillesdon, Stoke-Golding, Chetwode, Langley, Burnham, Eton College Chapel, and Olney spire serve, to a certain extent, to prevent our saying that there are no churches worth seeing in the county, and we will add to the list Maids Morton Church. This remarkably pretty little church is situated just one mile from the singularly uninteresting town of Buckingham,—the *beau ideal* of a thoroughly dull English town, with its ugly church, ugly town-hall, innumerable inns (there appears to be a drinking-shop of some kind or other to every four or five dwelling-houses). We see also the dull-looking shops with their stale fly-blown goods; the awfully respectable houses of the aristocracy of the place, and the "genteel villas" of the retired tradesmen, &c. A Continental town of the size would have its theatre, its *café*, its pleasure-garden, its concert-rooms, its band of music, its museum, and probably its picture-gallery; but in our English country towns there is absolutely no amusement provided for the people, and hence the innumerable public-houses.

Maids Morton Church is dedicated to St. Peter, and, although only a small building consisting of a single nave and chancel, small sacristy or vestry, a west tower and two porches, yet exhibits many features which are not commonly to be met with in village churches. Lysons gives the date of its erection at "about the year 1450." We confess we should be inclined to suggest a later date, judging from some of the detail. It is said to have been erected by two maiden ladies, daughters of the last Lord Peyvre, and there is much in the appearance of the building to favour this idea. No ordinary village church would have been constructed with the care and skill bestowed upon Maids Morton. The whole building, both within and without, is of ashlar, very neatly jointed, and laid in quite regular courses. The roofs of the nave and chancel are of oak, excellently carved and richly moulded. The porches, tower, and sacristy are vaulted in stone, with fan tracery. There is a good rood-screen, and a Norman font, ornamented with a kind of decoration resembling the expanded leaves of the sun-flower. There is a little stained glass, a Jacobean squire's pew, and a Communion-table of Charles II.'s period. The most beautiful object, however, in the church, is the remarkable sedilia, with rich projecting canopies, and an old painting of the Last Supper, extending across the back of the niches.

There are, however, one or two features about this building to which we would call special attention. They are, in the first place, the very original treatment of the belfry story of the tower. Contrary to the usual practice in England, the splay of the windows is external, and the great mullion in the centre is nearly the depth of the wall. The cusping of the enclosing arch is also rather uncommon.

The second feature which deserves attention is the very remarkable canopy over the western doorway, forming a kind of hood or hanging porch. Its design and treatment will be better understood from the sketch we give of it than from any amount of description.

The vaultings of the two porches and the sacristy also deserve special notice. They are remarkably elaborate examples of fan-tracery, and bear a strong resemblance to the vaulting of the two chantry chapels on either side of the choir of St. George's, Windsor. It is somewhat remarkable to find such work in a village church, and for this reason we are led to the conclusion which we have already alluded to, that Maids Morton Church may be looked upon rather as a "votive" church than as a parochial or village church.

The whole floor was originally composed of encaustic tiles, many of which remain. The monuments are not interesting. The stone which covers the grave of the two sisters who erected this beautiful building is situated in the middle of the nave; it formerly bore the brass effigies of two females, but these have disappeared.

It is stated that, within the memory of some now living in the village, every window of this most interesting church was full of stained glass, and the nave seated with carved oak benches; very little old glass, however, now remains, and the oak benches have given place to wretched deal pews!

NEW STABLING AND OUT-BUILDINGS, "THE LODGE," WALMER, KENT.

THESE buildings have been erected for Mr. Alex. Tod, from the designs, and under the personal superintendence of Mr. James Neale, F.S.A., of Bloomsbury-square, London. The main block comprises loose-boxes and stables for five horses, large coach-house, harness-room, five living-rooms and water-closet for the coachman, cistern, and box-rooms. Care has been taken that no living-rooms should be over or in any way connected with the stables. Separate accommodation is provided for the groom on the ground floor. There are lofts over the stables. The *flèche* is for ventilation, which is carried out on the Tobin system.

The out-buildings comprise cow-house, dairy, fowl-house, coals, wash-house, piggeries, earth-closets, &c. Special arrangements have been made for feeding the cows, and for taking the eggs from the hens' nests without disturbing the fowls. There is a loft over the cow-house, and also a loft over the fowl-house used for pigeons; the *flèche* shown on the drawing is the exit of the pigeon-house.

The walls, which are built hollow, are faced with Kentish rag, with ganged red brick quoins, sills, and dressings. The rag is hammer-dressed and laid in thin courses, varying from 2½ in. to 4 in. in thickness; the courses are brought to a horizontal bed at every 18 in. This means of laying the rag is similar to that used in some of the old churches in Kent. It has a quiet pleasing effect, and gives proportion to the buildings. The rag was prepared at the quarries of Messrs. Benstead & Son, at Maidstone.

The external timber work is painted a cream white, and the panels are pebble-dashed with small pebbles obtained from the beach.

The roofs are covered with the rich red tiles manufactured by Messrs. S. & E. Collier, of Reading. The hip-and-valley tiles have been purposely made from the architect's drawings to work with the tile courses. There are also purpose-made angular hanging tiles which overlap the angles of the dormers and prevent the wet driving in between the wood frames and the side tile hanging.

The facing bricks used are of a dark red colour, made by Mr. Charles Richardson, at Teynham. All the bricks have been rubbed. The moulded brickwork shown on the drawing is cut, rubbed, and set in putty.

The stables are fitted with all the modern appliances by the St. Pancras Ironwork Company. The wood is of pitch-pine. The space above the mangers is lined with delicate green tiles, and above is a frieze of salmon-tinted stamped plaster.

The stable yard is laid with blue brick, manufactured by the Kent Brick and Tile Company, at Pluckley.

There was no contract, with the exception of the stable-fittings, and, therefore, no temptation for "sea-side jerry building."

Mr. Redman, the clerk of works, engaged labour and material. Amongst the other trades not already mentioned were Messrs. Frost Bros., of Deal, for gas, water, and general plumbing; Mr. Steriker Finnis, of Dover, timber; Messrs. White Bros., London, cement; Messrs. Crease & Son, London, colours, &c.; Messrs. T. Potter & Sons, London, ironwork, gates, &c. Mr. William Webb acted as foreman; and Mr. Thos. Pulling undertook the painting and decorative work.

The stabling is well situated close by the sea, and surrounded by fine trees. There is to be telephonic communication between the stables and the house. The house, of which we may speak hereafter, is about 200 yards distant. It is now drawing to completion, having been enlarged at considerable expense from the designs of Mr. Neale.

PORTAL OF THE CHURCH OF SANTA MARIA, BELEM.

ABOUT two miles and a half from Lisbon, on the right bank and towards the mouth of the river Tagus, there existed during the middle ages a place called Restello, opposite the first and safest anchorage-ground for vessels after passing the bar of the port, being nearest to that for vessels preparing to leave for the Atlantic. On this spot the Infante Dom Enrique founded a small hermitage, and gave it to the Jesuits, of which body he was the administrator-general, with a view of rendering temporal and spiritual aid to mariners. Vasco de Gama, before starting on his momentous voyage of discovery to the East Indies, on July 8, 1497, is said to have offered up his humble supplications at the chapel attached to the hermitage, and again on returning, two years later, in September, 1499, to have rendered similar homage. This happened during the reign of Dom Manuel I. (1495—1521), surnamed the Fortunate, who determined to erect on the site of the hermitage a magnificent church in commemoration of the splendid achievements of the circumnavigator. This is the origin of the church of "Nossa Senhora de Restello," and the adjoining convent, in the vaults of which repose the remains of several kings of Portugal. The edifice, of the portal of which we give a view in this week's *Builder*, is a combination of the Ogive and "Plateresque" styles, and is one of the most elaborately adorned churches of Portugal. Its sculpture, both mural and statuary, is of the highest finish. The church contains a statue of its founder; a figure of the Virgin Mary, placed under a rich canopy; another of St. Michael the Archangel; and numerous saints in niches, also protected by canopies of filigree tracery.

There are comparatively few remains in Portugal of Mediæval architecture. The group at Belem, to some members of which we have before referred, is an important portion of them.

MEMORIAL CHURCH AT ST. PETERSBURG.

SIR,—We have received at the Royal Institute of British Architects, from the Foreign Office, by the courtesy of Earl Granville, a copy of the plan showing the site of the Memorial Church proposed to be erected at St. Petersburg to the memory of the late Emperor. As the Institute is now closed, and as the next number of our Journal of Proceedings will not appear until the middle of October, we shall esteem it a favour if you will publish a photo-lithograph of the plan, herewith enclosed, in an early number of the *Builder*. We venture to suggest that the conditions of this International competition, which were published by us on the 28th of July, should also be inserted, in order to explain the plan, especially as they have not yet been printed in your valuable journal.

J. MACVICAR ANDERSON, Hon. Sec.
WILLIAM H. WHITE, Secretary.

GEO. GODWIN, Esq.

We willingly publish the plan as requested, and we append the conditions as translated:—

"Extract from the *Journal de St. Pétersbourg*, May 28 (June 9), 1881.

In pursuance of a resolution passed by the Municipal Council of St. Petersburg to erect a stone Church, dedicated to the Russian Orthodox Ritual, and to be sacred to the memory of H.M. the late Emperor Alexander II., a competition is opened for the design of this edifice under the following conditions, viz.:—

1. The design must be so arranged that the church has three altars, the spot where H.M. the late emperor fell mortally wounded (shown on the plan by a cross) may stand in the centre or at the right angle of the western part of the church. This spot may be considered and treated as constituting the object of an annexed part of the edifice, though it must, nevertheless, form one and the same connected design of the church as a whole.

*** The foundation line of the west elevation of the church must not advance into the bed of the canal to an extent exceeding 7 ft., as indicated by the line *a b* on the plan, but the steps of the *parvis* of the church may be placed upon the bridge.

2. The basement is not intended to be applied to any purpose other than to provide room for the heating and ventilating apparatus and the storage of fuel.

3. The church must be designed to hold a congregation of 1,000 persons, upon the principle of allowing 7 ft. square to every sixteen persons.*

4. The position of the tower or that part of the building which is to contain the bells is left to the choice of the competitors.

* The number of sixteen persons per square *sagène* (7 ft. by 7 ft.) is fixed, because the Russian Orthodox Ritual does not admit of the worshippers being accommodated with seats during Divine service.

5. Competitors are also required to submit designs for the ornamentation of the bridge, which is to cover part of the canal so as to form a square in front of the church; and of the ornamentation of the part of the Palais Michel which will surround it.

6. The designs must include:—(*a*) Detailed plan of the church, two elevations, one a lateral one, and the other facing the park, and also a section; these drawings to be prepared to a scale of 1 in. (English) to the sagène (7 ft.). (*b*.) The west elevation and another section must be drawn to a scale of 2 in. (English) to the sagène. (*c*.) A general plan, on a scale of 1 in. to 5 sagènes. (*d*.) A perspective view of the church with its approaches. (*e*.) An explanatory memorandum stating, amongst other details, the cubic capacity of the church, computed in sagènes, and describing the nature of the materials to be used in the construction.

*** Competitors may elaborate the details of the building as they may deem fit.

7. Russian and foreign artists are both eligible to take part in this competition.

8. The designs must be submitted at the office of the Municipal Council of St. Petersburg at the latest on the 31st of December, 1881 (12th of January, 1882), at noon.

*** The general plan of the site whereon the church is to be erected may be had on application, either to the *Gérant* of the Town-hall of St. Petersburg, or to the offices of the newspapers in which the present notice appears.

9. For four designs sent in by the appointed time, which fulfil the conditions laid down in the present programme, and are allowed by the jury to be the best in order of merit, the Municipal Council will grant four premiums. For the first in order of merit, 2,500 roubles; for the second, 2,000 roubles; for the third, 1,500 roubles; for the fourth, 1,000 roubles.

10. All designs must be sent in in a portfolio, and not rolled up in a case.

11. Every sheet of the drawings, as well as the explanatory memorandum, must bear a motto chosen by the author of the design. The names, rank, and address, of each competitor, must be supplied in a sealed letter, bearing the author's motto on the cover.

12. All the designs sent in will be exhibited to the public during eight days in the town-hall. After the decision of the jury the successful designs alone will be exhibited again in public.

13. The jury undertake to publish a short memorandum setting forth succinctly the merits and defects of all the designs presented. The names of the premiated competitors will be published in the journals in which the present notice now appears.

14. The prize designs will become the property of the Municipal Council of St. Petersburg. The designs not selected for the prizes will be returned, together with the respective letters unopened, upon presentation of the receipts originally given by the *Gérant* of the Town Hall.

15. Members of the jury are debarred from participation, direct or indirect, in the present competition.

16. The premiums awarded will not entitle the successful competitors to take part in the construction of the church. The committee appointed by the Town Council reserve to themselves the selection of the architect to be entrusted with the execution of the works.

17. The jury consist of the following Members of the Council of the Imperial Academy of Fine Arts, viz.:—Professors A. Rézanow, D. Grimm, A. Krakas, and W. Schreiber; of the following Members of the St. Petersburg Society of Architects, viz.:—Professors R. Bernhardt and E. Gibert; and of the Mayor of the city, as well as of four delegates appointed by the Municipal Council."

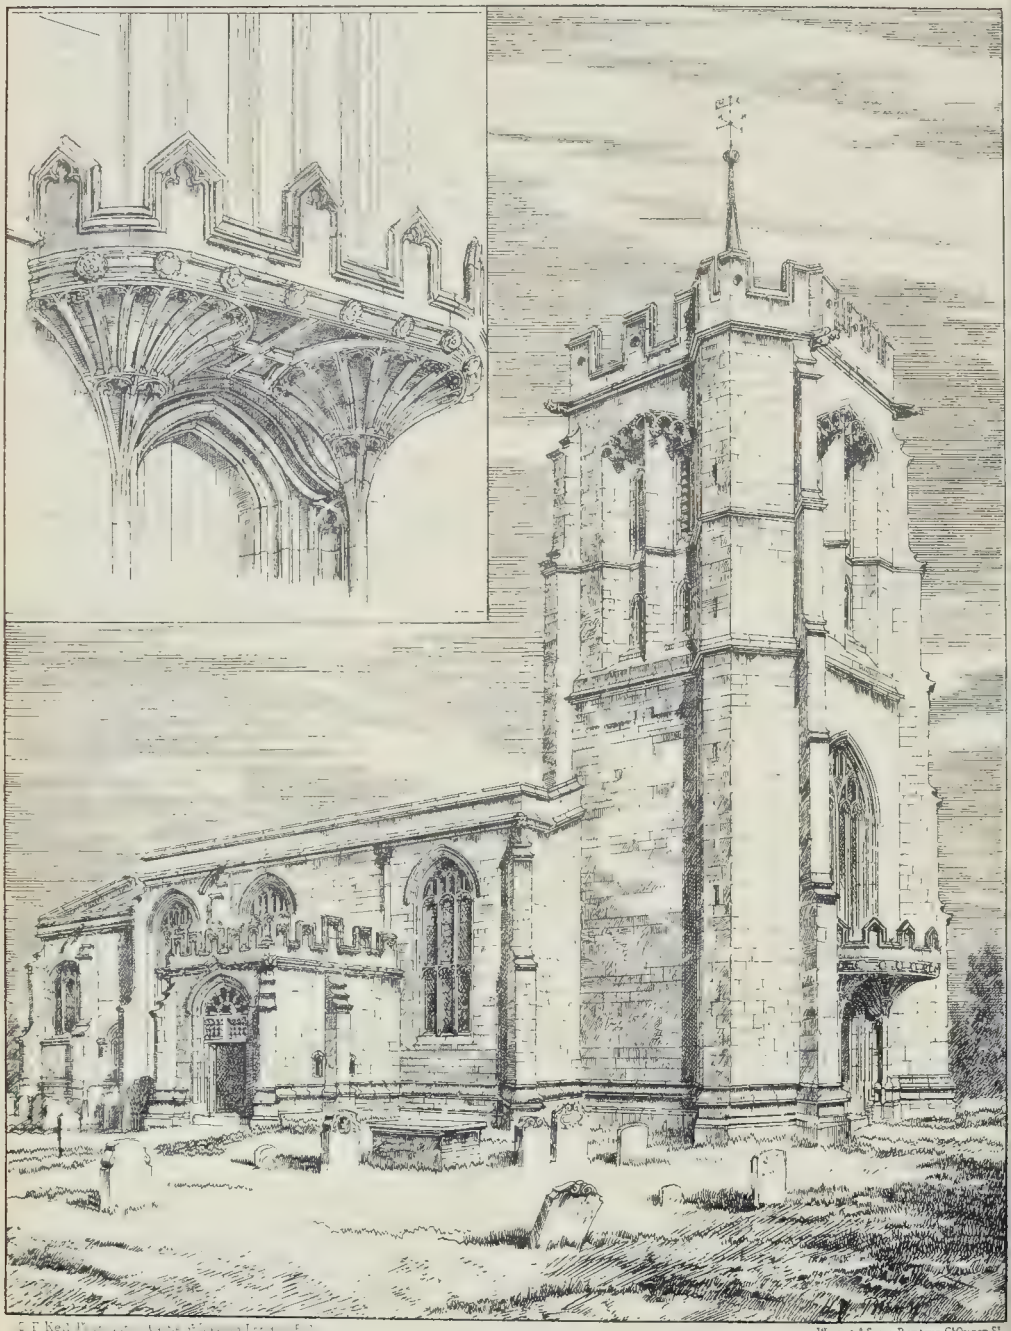
✠ The place where the Emperor was mortally wounded occurs at "1. arch. 4 *w*." of the line of the quay.

a. B. Limit of the foundations of the church.



The lines *c d e f g h i*, or *c d' e' f' g' h' i*, mark nearly the limits of the site intended for the church and the parts of the quay adjacent.

GAS AND WATER COMPANIES AND THE ROADS.

MR. JAS. LOVEGROVE, C.E., in his report to the Board of Works for the Hackney District as chief surveyor to the Board, says:—"The gas and water companies have made during the year, 1881, about 3,700 openings in the gravel and macadam foot and carriageways, and the total amount charged to them is 953*l.* 3*s.* 10*d.* The present system of breaking open the paths and roads for the purpose of cutting off water in cases of non-payment of water-rate, and after the lapse of a few weeks to re-open again for the purpose of laying on the water, is very unsatisfactory, and is one cause of constant disturbance of the highways. The system adopted by gas companies of cutting off inside the premises, clear of the highways, should be adopted also by the water companies. The highways are constantly being opened by the water companies because of the present objectionable system."

If some of the other Board surveyors will give similar statistics the damage done under the present system will become so apparent that a charge will be insisted on.

The Liverpool Autumn Exhibition of Pictures, now open, appears to be one of exceptional interest. Works by Briton Rivière, Sir John Gilbert, Yeames, Wells, Holman Hunt, and Alma-Tadema are included. A large picture by Mr. D. G. Rossetti, entitled "Dante's Dream," has been purchased out of the exhibition by the Corporation, and will be added to the local permanent collection.

PLAN SHEWING THE POSITION OF THE SITE OF THE CHURCH PROPOSED TO BE ERECTED TO MARK THE SPOT WHERE THE EMPEROR ALEXANDER II WAS MORTALLY WOUNDED.

NORTHERN ARCHITECTURAL ASSOCIATION.

LOCAL ANTIQUITIES.

THE annual meeting of this Association was held on the 6th inst., in the library of the old castle, Newcastle, the President (Mr. Septimus Oswald) in the chair.

The minutes of the last meeting were read by the hon. secretary (Mr. W. H. Dunn), and confirmed.

The President then read his address, in the course of which he said that the question of restoration or preservation of ancient buildings had more than a general interest to all in Newcastle, as the town possessed many such edifices, some of which it was projected to restore. There was the Black Gate, of which a good deal had been said lately, and the keep of the castle. The proposition to ask the Corporation to have the keep pointed with mortar or cement, under the direction of one of their engineering officials, filled him with alarm. How would they like to see the keep neatly pointed or covered with cement? No doubt decay of the stones was going on daily, but renewal of the most decayed portions from time to time would appear much the better course to pursue. In regard to the proposal to build a bridge from the roadway to the entrance of the Black Gate, he was doubtful, among other things, whether the safety of the entire building would not be endangered by the excavations necessary to such a course; but he made those suggestions with full deference to the opinion of those who had paid more special attention to the subject. He thought that anything done to the gateway should be more in the way of simple repairs than of what is called now-a-days "restoration," which too often meant the destruction of all remains of antiquity. Turning to another topic, he expressed the opinion that the appearance of our grand old churches and cathedrals was enhanced by the proximity of houses and other inferior buildings. The old houses seem to give a scale to a cathedral, and the gradual unfolding of the various parts of such a building added to its charm. It must be observed that he did not for a moment say that those petty structures should not be removed. Considerations of the picturesque were of little moment compared with sanitary and commercial improvement. He pointed out the new building at Amen Corner, which he was of opinion had the effect of "dwarfing" St. Nicholas's Church. He wondered whether those who passed the plans had ever considered its bearings on the "light and air" question as affecting the church, and thought public notice should be given of the intention to erect such buildings. The new churches in the North of England had very little of the picturesque about them. They all smacked of the T-square and drawing-board. In church and in street matters the rules of ecclesiastical commissions and local boards of health had a deadening effect on the imagination of the artist; but the additions and alteration of two or three centuries might render the churches more picturesque and historically interesting than they now are.

The Secretary said he had listened to the address with great pleasure. He had expected something to be said about building societies, but the President had been silent on that subject. As to the restoration of old buildings, that was a question on which they had different opinions; and he, therefore, should not express his opinion. But he must say that he thought the huge brick building which had been erected near St. Nicholas's Church, although a handsome building, out of place, character, and harmony with the ancient edifice. The corporation ought to give notice before they pass plans in which a building like St. Nicholas's Church is affected. The church had been handed down to us in trust, and we ought to be jealous of our old buildings and hand them down to posterity as a great trust. He moved that the best thanks of the meeting should be given to the President for his address, and for the way in which he had discharged his duties during his period of office.

The motion was seconded by Mr. E. D. Shewbrook, and carried unanimously.

The Secretary then read the annual report, which showed that the Society was in a satisfactory condition.

Mr. A. N. Dunn was elected president, Mr. S. Oswald vice-president, Mr. W. L. Newcombe treasurer, and Mr. W. H. Dunn, secretary.

CUMBERLAND AND WESTMORLAND ARCHÆOLOGICAL SOCIETY.

THE Cumberland and Westmorland Antiquarian and Archæological Society has just had its annual excursion, to which two days were devoted.

On the first day the party started in carriages from Egremont, under the guidance of Mr. Jackson, F.S.A., and proceeded by way of Calder Abbey, Gosforth, Seascale Hall, &c., back again to Egremont. At the head of Yeorton Brow, a halt of a minute or two was made, and Mr. Jackson pointed out a level field on the right-hand side as having been the site of Caernarvon Castle, described as "the original seat and still a possession of the family of Le Fleming." Nothing in the way of ruins, however, is to be seen. At Calder Abbey the party alighted, while the carriages drove back to Calderbridge, and a short paper descriptive of the abbey was read by the Rev. Canon Knowles. The ruins were then inspected, and Mr. Jackson and Canon Knowles made some remarks upon three mutilated stone effigies of mailed knights which lie against one of the walls; while Mr. Ferguson, F.S.A., Carlisle, directed attention to what is styled a cresset stone, a square block of red sandstone, having sixteen circular holes. These stones, several of which have been found about old abbeys, had long puzzled antiquaries; and Mr. Lees, of Wreay (a member of this society) claims the credit of discovering their use. It was the business of the cook in the monastery, it appears, to keep these holes filled with tallow or fat, into which a rush was set; and thus fitted up, the cresset stone was used to illuminate the dormitory. A walk along the romantic path by the Calder brought the party to St. Bridget's, Calderbridge, the attraction here being a curious portable or super altar, one of a number which had been blessed by the Archbishop of York about the middle of the fifteenth century, by permission of Pope Nicholas V. The altar, on which several small crosses are sculptured, was found at Calder Abbey, and the vicar of St. Bridget's, the Rev. A. G. Loftie, has had it secured in a frame in a corner of the chancel. The carriages were again put in requisition, and the party drove on to Gosforth Church. Here the curious old cross in the churchyard was inspected, and discussed. Canon Knowles thought the cross was of twelfth-century work, while Dr. Parker considered it much earlier, and narrated what local tradition said on the subject. This was to the effect that the cross had been erected by Danes who settled at Gosforth, and were converted to Christianity. Mr. Calverley thought that some of the figures on the stone indicated the binding to a rock with chains of Loki, the Scandinavian Beelzebub; and Canon Knowles agreed with Mr. Calverley that the carving was of a half secular and half religious character. The party next visited the church, and the Rev. Mr. Wordsworth, the rector, exhibited some quaint old communion-plate, some of it of pewter, and a black-letter copy of the Book of Homilies, folio, 1633. After some little delay, the carriages started again for Seascale Hall, the members gathering in a field adjoining the hall. Mr. Jackson pointed out that the field was surrounded on three sides by water, and was altogether exceedingly well adapted for a fortification; and as it must have been close to the Roman way to the various camps along the coast, he thought it not unlikely that it might have been the site of a camp. To test this supposition, Mr. Joseph Robinson, of Maryport, a member of the Council, and an enthusiastic explorer, had arrived at the field an hour or two before the party reached it, and with the permission of Mr. Walker, he had made a series of excavations on a small scale in various parts of the field; but his labours had met with no reward, no stoneware being discovered. Mr. Ferguson did not think it likely there ever was a camp here, as the field was commanded by rising ground, whence it could be rendered untenable by slings or arrows. The old church of St. Bridget was visited by some of the party, and on the return to Egremont in the evening the excursionists dined at the Globe. Subsequently the annual meeting was held, and papers were read by the Rev. W. S. Calverley on "Illustrations of Teutonic Mythology from Early Christian Monuments in Brigham and Dearham Parishes"; by Mr. Jackson on "The Mesne Manor of Thornflatt and its Owner, 1656-59"; and by Mr. Ferguson on "Church Plate in the Gosforth Deanery."

On the second day, after breakfast at Egremont, Mr. Ferguson read a paper, by Mr. G. T. Clark, F.S.A., on "The Mediæval Defences of the English Border." Mr. T. L. Banks, A.R.I.B.A., then read a paper on Egremont Church. The party afterwards proceeded by train to Ravenglass to inspect the excavations which, for some time, have been going on at Walls Castle, as the remains of a Roman villa, near Walls Farm (the property of Mr. Aaron Brown) are popularly called. Mr. Robinson has been lately excavating here, with most gratifying results, a hypocaust having been discovered, thus satisfactorily dispelling any little doubt that might remain as to the villa being indubitable Roman work. Walls Castle and the adjacent Roman camp were fully described in papers prepared by Mr. Jackson and Canon Knowles, and read at the Society's meeting at Wigton in September, 1876. Mr. Jackson referred to these papers, and described the nature of the excavations and the result of the discoveries made, and he warmly thanked the owner of the ruins, Mr. Brown, for having so kindly given them *carte blanche* to cut up the ground. Mr. Robinson and Mr. Ferguson also spoke, both gentlemen stating that the villa was unequalled by any remains of the kind either in England or France, there being no Roman villa elsewhere which stood over 12 ft. above the ground. Canon Knowles expressed a hope that the ivy with which the building was overgrown would be cut down, and it was stated that Mr. Brown intended to do this.

THE NEW NORTH DOCKS AT LIVERPOOL.

THE new North Docks at Liverpool, opened by the Prince and Princess of Wales on the 8th inst., as already mentioned, practically complete the great northern development of the Liverpool Docks, as authorised by the Act of 1873, which empowered the Dock Board to make an expenditure of 4,100,000*l*. The great northern basin, which, with its entrances, forms the most important feature of the work, has an area of about seven acres, and a depth of water at spring tide of 44 ft., while even at low water there are 12 ft. over the sill. The Alexandra Dock is not only the largest in Liverpool, but it has more quay and shed accommodation than any other in the world. The following is an official description of the new works:—

In 1873 the Mersey Docks and Harbour Board, the trustees appointed for the management of the docks at Liverpool and Birkenhead, having in view the necessity of providing additional dock accommodation to meet the increasing tonnage and size of the vessels trading to and from the port, instructed their engineer, Mr. George Fosbery Lyster, to prepare plans for carrying out that object, and these, after careful consideration by the dock authorities and the shipping as well as trading interest of the port, were approved, and the authority of Parliament obtained to borrow, on the security of the dock rates, the sum of 4,100,000*l*. for the purpose of carrying out the works. The works authorised to be constructed under the above powers consisted of extensive additions to the dock system at the north and south ends of the dock estate on the Liverpool or eastern shore of the river Mersey, and both sections have, during the last eight years, been pushed forward with all the speed that the varied nature of the operations involved in their construction would admit. The section of new docks opened by his Royal Highness the Prince of Wales are situated at the extreme north end of the city, a distance of three miles and a half from the Liverpool Exchange, and within the borough of Bootle. The entrance for shipping is through what is known as the Canada Basin, into which the tide of the Mersey ebbs and flows, and originally formed the vestibule of the most northerly approach to the then existing docks in this locality. This basin has been considerably enlarged and deepened, and its entrance widened from 250 ft. to 400 ft. On each side of its entrance piled timber jetties or piers projecting into the river are intended to be constructed, one being already completed, for facilitating the ingress and egress of shipping entering the docks at this point, as well as for assisting the sluicing operations for keeping the fairway and entrance clear of silty deposits. On the northern side of the basin are formed two docks or passages through which vessels enter the newly-constructed system, the first being the Langton Dock, having a water area of eighteen acres, with quay or berthing space

4,000 ft. in length. In connexion with and opening therefrom on its eastern margin are two graving-docks, each 951 ft. in length. These are so arranged that whenever required they can be subdivided into four docks, each capable of allowing the largest class of vessels to be overhauled or repaired. On the quay, between these graving-docks an important block of buildings has been erected, containing powerful engines and machinery, by Messrs. Hick, Hargreaves, & Co., of Bolton, for the purpose of pumping the graving-docks; also powerful engines for supplying the motive power for actuating the hydraulic machinery for opening and closing the dock-gates, bridges sluices, working cranes and other machinery throughout the system. The latter engines and the hydraulic appliances have been supplied by Messrs. Sir W. G. Armstrong & Co., of Newcastle-on-Tyne.

A number of dwellings have been erected on the "flat" system over this building for the accommodation of the foremen and enginemen. A lofty tower for the purpose of enclosing the accumulator has been built to a height of 120 ft. above the quay, also utilised as a clock-tower. The architecture of this group of buildings is Gothic in feeling.—somewhat freely treated to adapt it to a building of such an exceptional character. Northward of these graving-docks, and also leading out of the eastern side of the Langton Dock, is a branch dock having a water area of three acres, with 2,013 ft. of quay berthing space. Upon the south quay of this dock a hydraulic crane, capable of lifting 100 tons, is in course of construction for the purpose of dealing with heavy boilers and machinery. At the northern quay of the Langton Dock two passages are formed communicating with the dock, specially constructed to meet the requirements of the large and increasing size of steamers using the port, and named at the opening ceremony by her Royal Highness the Princess of Wales the "Alexandra Dock." This dock is 1,600 ft. in length from north to south, and has three branch docks, ranging from 1,100 ft. to 1,338 ft. in length, leading in shore from its eastern quay, and extending to within a short distance of Regent-road, the main thoroughfare flanking the dock at this point. This dock, with its branches, has a water area of 44½ acres, and 11,814 ft. in length of ships' berthing space. To the northward of the Alexandra Dock another dock is in course of construction, having a water area of sixteen acres and 4,000 ft. of quay berth. The quays surrounding these docks are provided with capacious and substantial lock-up sheds of from 80 ft. to 95 ft. in width, for the protection of cargo, and are in direct communication by road with the city, and by rail with the stations of the Lancashire and Yorkshire, the London and North-Western, the Midland, the Manchester, Sheffield, and Lincolnshire, and the Great Northern Railway Companies.

A most important feature in the design of these docks is that of laying the sills of the entrances at the level of 12 ft. below the old dock sill datum, thus giving a depth of water on an average neap tide of 23 ft. 7 in., and on an average spring tide of 30 ft. 10 in., and enabling the general class of vessels using the port to enter or leave the docks at all tides throughout the year, without the delay, expense, and risk of loading and discharging a part of their cargo in the river on low neaps, as has been the case hitherto. On the east side of the main entrance by which vessels enter this new group of docks, a large block of buildings is in course of erection, containing residences for the dockmaster, piermasters, and gatemen; also offices for the administrative staff. The general appearance of these erections is that of a solid block, the yards and drying-ground being arranged in a quadrangle approached by a covered archway. The architecture is a free adaptation of Domestic Gothic, red brick being used instead of stone to obtain the necessary relief. The dock walls are of a most substantial character, and are for the most part built of cement concrete, faced with the red sandstone of the district, the coping being of granite. The entrance walls are faced with granite. The graving-docks, with the exception of the steps and slips, which are granite, are built throughout of concrete. The whole of the dock-gates are constructed of greenheart timber, this being considered by the engineer as the most durable description of timber for this class of work. The additional accommodation for the trade of the port provided by the docks just opened by his Royal Highness, and those at the south end in course of construction, will amount to about 110 acres of water area, with over 6½ miles of quay berth.

It may be added that in carrying out this great work, Mr. Lyster has been assisted by Mr. Fielden Sutcliffe, assistant dock engineer, and latterly by Mr. Lyster, jun. The contractor for the excavations in connexion with these works was Mr. Chas. Tottenham. It is satisfactory to be able to add that the new works have so far been executed without any serious mishap or casualty.

THE LONDON AND ST. KATHARINE DOCKS.

SOME interesting statements were made at the half-yearly meeting of the London and St. Katharine Docks Company, which has just been held. The company may be said to be one of the largest corporations in London, its capital being about 10,000,000*l*. The company's revenue for the six months ending in June last was 555,446*l*. The expenses, however, were unusually heavy, amounting to no less than 409,179*l*., leaving a profit of 146,266*l*., of which 73,021*l*. was absorbed in interest charges, including 12,131*l*. on account of the Victoria Dock Extension. The dividend declared was at the rate of 2½ per cent. per annum only. Adverting to the large outlay which had been incurred in the Victoria Dock Extension, the chairman observed that to his mind the most satisfactory feature was that with regard to what was likely to be the future course of the commerce of the country they had adopted those means which would most likely be beneficial to the company. He remarked that steam and telegraphy had exercised such an influence that it was no longer necessary to hold in our ports those stocks of goods which were formerly held. They had imported something like 40,000 tons more goods than in the corresponding period of last year, in spite of which their stock of goods at the close of the half-year was about 4,000 tons less, and notwithstanding the larger quantity of import goods landed there had been an improvement in the receipts on that head, of only 8,000*l*. When, however, they came to the consideration that in future the trade of this country was more likely to be a transit trade, they would see that in every item which was likely to be important in the future they had had a very substantial increase. Their export rates showed an increase of over 8,000*l*., their tonnage rates on shipping an increase of over 10,000*l*., and their rates for discharging cargo an increase of 9,000*l*. Grain was likely to be one of the largest trades of this country in the future, and whereas in 1880, out of 496,000 quarters in the port, the company had only had 14,000 quarters at the end of the last half-year, out of 175,000 quarters no fewer than 76,500 quarters had been in their docks. Another feature of promise was that they had made an agreement which would bring a large coal traffic into their docks, particularly into their Royal Albert Dock.

THE NEW GRAMMAR SCHOOL AT CARLISLE.

ON the 6th inst. the foundation-stone of the new grammar school, which is to be built at the corner of Spring Gardens and Swifts-lane, Carlisle, in accordance with the provisions of the scheme of the Charity Commissioners, was laid by his Grace the Duke of Devonshire, K.G. The Governors having secured the site, at a cost of 3,250*l*. (towards which the Duke of Devonshire contributed 500*l*.), invited eight firms of architects to send in plans, and five responded to the invitation. Finally, the first premium was awarded to Mr. G. D. Oliver (of the firm of Messrs. Hetherington & Oliver, of Carlisle), Mr. E. R. Robson, of London, being second, and the successful competitor was instructed to prepare specifications and detailed drawings. Last month tenders were invited, and the successful contractors were Messrs. Beaty Bros., Carlisle, 4,591*l*., for the builder's work, and Messrs. H. & R. Court, Carlisle, 2,746*l*., for the joiner's work, making a total of 7,337*l*. To this must be added the cost of painting, slating, and furnishing, and it is thought that the total cost will be at least 10,500*l*.

The main building will (according to the *Carlisle Journal*) be in what is called the Domestic Tudor style of architecture, the materials used for facing the external front walls being red sandstone, the quoins and dressings being "skew chiselled." The main buildings will have a south-east aspect, facing Swifts-lane, and set back 70 ft. from the line of the road, so as to leave a good carriage drive in front. The western elevation is set back several feet from the Spring Gardens-lane. On approaching the new school from Albert-street, the most striking feature in the building will be the central tower, in which the main entrance will be placed, with an oriel window above the porch, and a conical roof. On the right of the central tower, on the ground-floor, are the assistant master's sitting-room, the dining-hall (36 ft. long by 18 ft. 6 in. wide and 14 ft. 6 in. high), with a large bay-window, capable of seating sixty to seventy boys; and further eastward stands the head master's house, with accommodation for about thirty boarders. On the left side of the central tower, on the ground-floor, are the Governors' board-room and a series of class-rooms, which extend northwards in what may be called an annexe of the main building, connecting it with the large schoolroom or prayer-hall, which will apparently occupy the position now taken up by the farm buildings at the corner of Spring Gardens-lane. This hall, which can either be approached by the main corridor which runs from the central tower past the doors of all the class-rooms, or by a covered way leading from the playground and the boarding-house, will be 87 ft. long by 28 ft. 6 in. wide, and runs east and west, with a large window at each end. It will seat about 300. At the south-west corner of the building a chemical laboratory is provided for. The entrance for day scholars will be in the west front, about midway between this laboratory and the large schoolroom or prayer-hall. In arranging the class-rooms special consideration has been given to the purposes for which they were intended; the drawing-class room, for example, being provided with suitable roof-lights.

THE NEW MARINE OBSERVATORY OF HAMBURG.

IN the year 1874, a central institution was established at Hamburg for marine meteorology and storm-signalling for the entire German Empire. The want, then and since felt, of a building specially designed for the scientific purposes in question, has now been met. A structure has been erected, which is described in the German press as not only expressly designed for the purpose required, but as also being an ornament to the city from an architectural point of view.

The site was a gift on the part of the senate and municipality of Hamburg. In the latter part of 1878, Messrs. Kirchenpauer & Philippi (architects of the chronometer-testing house) were entrusted with the preparation of designs for the work, and their plans and estimates were finally approved on July 30th, 1879. Various preparatory works (necessary for securing a ready access to the site) having been carried out, the tenders of August Maas as general contractor for earthwork, bricklaying, asphalte work, &c., was accepted, as also that of the Hanseatic Building Company for stone work; both contracts having been signed on October 3rd, 1879.

During the first half of the year 1880 the work progressed rapidly, and the building was roofed. For the laying-out of the gardens, &c., H. Ohlendorff contracted, and by June, 1880, the magnetic pavilion or compass-observatory was ready for use. The ceremonial of laying the foundation-stone took place on June 15, the stone being placed in a space reserved for it in the entrance.

The internal work has been since carried on with activity, and the opening by the Emperor in person was announced to take place on the 14th inst.

A New Substitute for Timber.—It is reported from America that Mr. S. W. Hamilton, of Lawrence, Kansas, has invented a process for producing what the Americans call "lumber," from straw, by a process which is kept secret. It can be made to any required length, and up to 32 in. wide, will hold nails as well as wood, is water-proof, and takes a high polish. It is about the colour of oak, with a specific gravity of one-fifth more than that of well-seasoned black walnut.

THE ROYAL COURT THEATRE, LIVERPOOL.

THIS new theatre, which stands upon the site of the old Amphitheatre, was opened on Saturday, the 10th inst. The rebuilding has been carried out from plans and drawings by Mr. Henry Sumners, F.R.I.B.A., of Liverpool, and under his supervision. Mr. Sumners found it necessary to sacrifice the whole of the interior of the old theatre, and consequently the gallery, circle, boxes, and stage had to be totally demolished and swept out of the place, leaving nothing but the four bare walls. It was found in clearing away the old timbers for the purpose of remodelling the theatre that there was not a faulty piece of wood in the whole of the place. The T beams spanning the wide building are as good as when first put in their places,—more than half a century ago,—the queen-posts being of African oak. The brick walls showed, in every instance where they had to be cut, that the old Liverpool hand-made bricks have never been excelled. The mortar, too, looked more like mountain limestone than the compound used nowadays. On the 1st of March last, Mr. Sumners entered upon the scene with a body of workmen, who began the work of demolishing the old building with great energy. The rebuilding, decorating, furnishing, and fitting up has proceeded with the same celerity, and in the short space of six months the building stands complete. The stage and all its complicated mechanism has been constructed by Mr. John Byrne. The rock under the stage has been taken out to a depth of 27 ft. This renders it possible to lower scenes through spaces in the stage with great rapidity. Moreover, what is technically called the "gridiron," upon which the blocks and drum winches are fixed, is now about 72 ft. above the stage. The facilities thus gained for raising part of the scenery and sending the remainder down into the sinking in the rock enable the stage to be cleared of all the scenery used in any piece in a very few seconds. The whole of the apparatus for lighting the stage and the other working parts of the theatre has been constructed by Mr. Watmough. The gas-meters are inclosed in brick chambers distinctly set apart from the stage and entirely clear from and not under any part of the auditorium. An ample main for the supply of water for scenic and other purposes has been laid on to the stage and other parts of the house by the city authorities. The auditorium is narrower by 10 ft. than it was before the rebuilding took place, being now between 60 ft. and 70 ft. But the distance from the footlights to the wall at the back of the stage is greater than before, the proscenium wall having been brought forward. Notwithstanding this, owing to the removal of some useless rooms at the Great Charlotte-street end, the auditorium is as large as before. The house will, it is thought, accommodate about 3,000 people. All the entrances are ample in width and easy of access,—that to the boxes, dress circle, and stall is from Queen's-square, and is approached by two folding doors, which are each 6 ft. wide. These doors lead into an entrance-hall about 21 ft. in width, the floor of which is inlaid with Burke's mosaic work. Iron is freely used in the construction of the galleries. The pit is entered, on a level from Great Charlotte-street, by a short passage of 7 ft. in width. The pit floor is raised at the back, and has an incline to the stage of 1 ft. in every 18 ft. The pit seats are of pitch pine, highly polished. The entrance to the gallery is also from Great Charlotte-street, up a well-lighted and capacious stone staircase. It has been the study of the architect to avoid putting a single seat in the theatre, from which the spectator cannot command a good view of the stage. The ceiling, proscenium, and front of the boxes, and also the fronts of the dress-circle and gallery, have been covered with Goodall's fibrous plaster, the materials of which is light, and can be moulded into the most elegant forms. The curtain is of crimson velvet, bearing the royal arms, woven in gold. The act drop, which is the work of Mr. T. P. Hall, of Manchester, represents Thespis reading his play to an assemblage of villagers. On the Queen-square front of the building there are five heads carved upon five medallions of Stourton stone. The middle one is Shakspeare, and he is supported on either side by two busts, one emblematical of tragedy the other of comedy. A bust of Mozart is at the west corner of the front, and of Handel at the east. The carving has been done by Messrs. Norbury, Upton, & Patterson, of Liverpool. Dressing-rooms are numerous and conveniently situated; they are supplied with hot and cold water throughout. The oxyhydrogen gas-holders, for producing limelight effects are the work of Mr. Henry Whitehead, Gaythorn, Manchester. The stage is separated from the auditorium by a brick wall running up to the roof of the building, and the auditorium is again separated in a similar manner from that part of the building containing the entrances and crush-room.

Subjoined are the dimensions of the house:—

	ft.	in.
From curtain line to dress-circle front	40	3
From curtain line to gallery front	42	0
From curtain line to wall at back of pit	70	8
From curtain line to back of stage	50	0
Width of stage	62	0
Height of stage to gridiron	50	0
Depth of stage to mezzanine floor	6	0
Depth of stage to well of stage	27	0
Height of ceiling from pit floor	40	0
Height from pit floor to dress-circle tier	13	2
Height from dress-circle tier to gallery tier	25	7
Height and width of proscenium opening, 28 ft. by 23 ft.		

The brick and rock work has been done by Messrs. Roberts & Robinson, of Liverpool; the woodwork by Mr. Thomas Urmson, of Liverpool; the slating and plastering by Messrs. Johnson & Son, Liverpool; and the ornamentation by Mr. Goodall, Liverpool.

THE "INNER CIRCLE" RAILWAY COMPLETION.

ON the 5th inst. the Lord Mayor of London "cut the first sod" of the works necessary for the completion of the "Inner Circle" of railways. The circle is incomplete by reason of the break between Aldgate and the Mansion House. The subject of the completion of this railway has, as is well known, been the source of much discussion and litigation, but it has at last been settled, chiefly by the advance in the contributions to be made by the public and City authorities to the Metropolitan and District Railway Companies. The Commissioners of Sewers at first offered to give 250,000*l.* towards the project, but finally consented to give 300,000*l.*, which, with the 500,000*l.* promised by the Metropolitan Board of Works, makes the subvention of 800,000*l.*, which will come out of the public pocket to assist the railways in their scheme. The result of carrying out this work of completion will be very advantageous to the public, as the underground communication between the different parts of London will not only be improved, but also the thoroughfares under which it will barrow. The cost of the public improvements to be effected along the line of route is estimated at 1,200,000*l.*, so that the companies will pay 400,000*l.* for their right of way, and 800,000*l.* for the widening of old streets and making of a new one. By this means a fine line of thoroughfare will be established from the Houses of Parliament to the Tower by way of the Embankment, Queen Victoria-street, Cannon-street, Eastcheap, and Tower-street. Starting from the Mansion House, the new line will be in a tunnel under the eastern portion of Cannon-street, going past the King William Statue and under Eastcheap, the houses for that purpose being pulled down, so as to gain a total width of 60 ft. The line will then pass on by way of Little and Great Tower streets as far as Mark-lane. At this point a new street will commence, passing round by a curve on the north side of Allhallows Church, and terminating in Trinity-square. The railway will, however, continue its underground course, curving round in a northerly direction so as to cross the Minories and run at the back of that thoroughfare up to Aldgate. Mr. Walker is the contractor, and it is anticipated by Sir Edward Watkin that the work will be completed in about eighteen months.

RAMSGATE.

THE Smack Boys' Home, lately erected in the Royal Harbour, Ramsgate, from the designs of Mr. Alfred R. Pite, of Bloomsbury-square, was opened last week by the Marchioness of Conyngham. The work has been carried out by Mr. W. Martin, contractor, of Ramsgate, at a cost of 2,000*l.* The accommodation provides for sixty boys, having, on the ground-floor, spacious messroom and offices; and on the upper floors, dormitories with double berths, work-room, washhouse, laundry, and locker-room. The institution, it is anticipated, will be self-supporting; but the present building has been erected by voluntary subscriptions.

USES OF FAURE'S ACCUMULATOR IN ELECTRIC LIGHTING.

AT a meeting of the Mathematical and Physical Science Section of the British Association, Sir W. Thomson read a paper on this subject. He observed that the first and most obvious use of Faure's accumulator was to produce the electric energy at a most convenient time, and keep it in store until it could be most conveniently used. It was obvious that great economy and important practical results were to be obtained by the use of such a system, provided the expense of the storing material, and the magnitude and bulkiness of the apparatus that it involved were not prohibitory,—were not such as to run away with whatever gain there might be in the principle. The subject was altogether in its infancy, and we must wait for greater information, both as to its practical and economic side. So far as estimating electric quantities was concerned, we must hold our hands until incandescent lamps were given us, with a statement that they would burn at so many candles power, approximately, when so many volts were applied to them, and for such and such a time. One use of the Faure accumulator, which was obviously of great value, was that of connecting the working machine with the dynamo-machine, in order to fulfil the first condition of giving greater regularity than could be attained, or was practically attained, without it; and, in the second place, of being ready to sustain the light for several hours after the driving machine was stopped.

Dr. C. W. Siemens said, if Faure's battery could be used as a store to be resorted to at any moment by means of an automatic arrangement, there could be no doubt that very valuable assistance would be given to the practical electrician in carrying out almost every application of electricity, not only to lighting, but to the transmission of the power. The only danger was that, if the sources of power failed, there was an interruption, and the effect of these interruptions was very trying, in the case of lighting especially. The arrangement shown by Sir Wm. Thomson seemed very efficacious and valuable.

Mr. Swan, of Newcastle, the inventor of the incandescent light, expressed satisfaction with the paper of Sir Wm. Thomson. He thought, however, there was some difficulty in the way of adopting his system. Under existing arrangements the accidental throwing off of a belt extinguished the lights when the dynamo-electric machine was exclusively depended upon for producing the current. It seemed that the addition of Faure's battery to this method of supply (especially when used as Sir Wm. Thomson proposed to use it, viz., as a store and a regulator, with the addition of his automatic circuit opener) was the very thing wanted to make electric lighting all that was needed. He had recently experimented as to the use of the Faure battery in connexion with his own lamps, and he found it to work admirably. He could not express the delight he felt in the prospect that lay before them of using the battery in connexion with our other means of producing electric currents.

RUINING STONEHENGE.

WE can scarcely believe what we hear from Stonehenge. According to the *Salisbury Journal*, "the only remaining outer trilithon on the north-eastern side of the rings has been bolstered up by means of a gallows-like wooden erection, very similar in construction to that which supported Temple Bar during the last months of its existence. This is placed transversely beneath the upper stone; and, as it is of a very substantial nature, it completely destroys the picturesque effect of that side of the ruin. The trilithon in question seems to us to be quite as erect and safe as any of the stones, and probably more so than the majority of them; and we cannot conceive why it should have been chosen as a *corpus vile* for the 'restorers' to begin their experiments upon. The huge pillar which inclines inwards on the south-western side will, presumably, be next taken in hand, for, since the work has been commenced, it is but natural to suppose that it will be completed, and that all the stones will ere long be safely buttressed by a number of unsightly props and scaffoldings." This unnecessary disfigurement of a national monument of extreme value and interest should at once be protested against by all who have any influence likely to weigh against its perpetration. Who is responsible for it? It seems almost like a piece of spite in reply to those antiquaries who

have recently been urging the necessity of setting upright some few of the stones that are obviously slipping. No individual should have it in his power to damage such a monument as Stonehenge, even under the guise of protecting.

VERGERS AND CATHEDRALS.

SIR,—In your number of the 13th ult., under the heading "A few Modest Suggestions," for the approaching meeting of the British Association at York, your correspondent, "F.S.A.", suggests *inter alia* an intercession with the Dean to allow the cathedral to be seen without the intervention of an "illiterate verger," and he follows with an account of an infliction he underwent from one of those custodians whom it seems to be the peculiar province of Deans and Chapters to appoint. It is devoutly to be hoped that the authorities, acting on this seasonable suggestion, mercifully spared the members of the Association who were gathered together in that grand old city a repetition of the infliction to which "F.S.A." refers, and have permitted the Minster to be seen without the irritating accompaniment of a string of mild jokes.

When will Deans and Chapters recognise the fact that they are only the trustees of these glorious buildings, reared by our pious forefathers to the glory of God, and handed down to us as a precious possession, to be held and preserved with loving care, for generations yet to come? Let us for a moment consider the feelings of one of our educated Transatlantic cousins, who, on visiting the "old country," as some still affectionately term it, enter for the first time one of these grand temples and experience the (to them) new sensation of its strange and weird magnificence bursting on their view with all its grand effects of light, form, and colour, and then, sir, like a spider from his web watching a fly, pounce comes the aforesaid custodian, and with what "F.S.A." calls his "miserable twaddle," leads them like a flock of sheep the accustomed round. What, indeed, can the enlightened foreigner think of us? I, too, have just undergone a similar infliction, when, a few days since, I visited one of the finest of our cathedrals,—the only example, I believe, conceived, planned, and carried to completion in one style of architecture. Would that I and my friends had been left alone to the quiet enjoyment of the feast; but no, the moment the choir-gates were entered down comes the verger, "This way, please, I am just going round; that's the organ divided into two parts, the pedal pipes and the 'bellus' is in the transept"; and thus through the show like the keeper at a menagerie. "That's a wonderful brass; notice the hares and rabbits; that screen was removed from another part of the cathedral; they employed an 'architec' at the end of the last century: he did everything all wrong, and they have been undoing everything he did. That's a cope-chest; they used to wear copes of velvet, embroidered with gold, and that's where they were kept. Notice the 'cullums,' they are all of Purbeck marble; they can't get any of this size now. That's a splendid monument; it cost 600*l.* to restore; you see the figure of the lady is placed over her husband, because she was higher in rank." But the climax was reached in the chapter-house when beginning the description of the quaint sculptured groups at the creation, we were told, "That's Eve, with the apple in her hand, a-giving it to her husband. That's Joseph, being put in the pit, head downward." But, enough of this. The description was continued in a kind of nasal chant until the door was again reached. "You will find it all in the Guide-book, price one shilling." I was taken to a table, and told to enter my name in the book, and to put 6*d.* in the bag for each of the party. To this fee I make no demur. Few would object to contribute towards the maintenance of this glorious pile. I must, moreover, acknowledge the politeness and attention of our guide; on this ground no complaint could be made. I asked to see the library, but was told that the key was kept by the librarian, and that it was only shown on certain days. Why only on certain days? Is it too much to expect that every part should be open without restriction?

In conclusion, may I venture on a suggestion that the Dean or some one of the cathedral dignitaries should disguise himself, and, like the "Amateur Casual," undergo the infliction in person? But, if this be declined as quite too painful, send a shorthand writer, and let him take down *verbatim et literatim* this miserable stuff, from which the unfortunate visitor is unable to escape. Lay this before the Chapter at their next meeting, when, if they will be at the trouble to read it, perhaps it might be "reformed altogether," and at my next visit I may find some more intelligent guide, or, failing this, be permitted to wander in contemplation and peace. C. T. H.

SIR,—I was surprised to see the letter by "F.S.A.," complaining of want of attention, &c., at York Minster. Permit me to say that three months ago I was shown over by one I thought a model of politeness and intelligence. My visit was a long one. I made several notes, and spent an hour in the crypt,—in fact, gave an unfair amount of trouble, I thought, for a stranger. I should like some of your readers, particularly "F.S.A.," to visit the Abbey at St. Denis, and experience what rudeness really is. I do not think they will find it in any abbey in England,—certainly not at York Minster.

SYDNEY SMIRKE.

*** This may be quite correct, doubtless is so, but it does not at all affect the correctness of "F.S.A.'s" complaint, which has since been confirmed by other correspondents. "F.S.A." said nothing of "rudeness," he simply objected to the illiterate twaddle that was talked.

THE BRITISH ASSOCIATION AT YORK, SEPTEMBER, 1881.

"A Picture in Little."

A's the Association of far-spreading fame,
B stands for British, who gave it its name.
C's Correspondence enormously great;
D's for the Dinners the visitors ate.
E's for the Engines which didn't explode;
F is the Fun travellers had on the road.
G stands for Gossip, so tripping and light
H Howard Castle, sightseers' delight.
I Indian presents by our Prince sent down,
J for the Jubilee held in the town.
K for the Kindness evinced everywhere
L Local secretaries with patience rare.
M for the Minster, so stately and grand
N for the Noodles who won't understand.
O is the Ouse, which enriches the town;
P is the President, of wide renown.
Q stands for Queries, excuse for much talk;
R for the Railway which took folks to York.
S is for Science, the real *raison d'être*,
T for Tea-table talk, and *tête-à-tête*.
U's for the Units too late for each outing;
V is the Voice which grew hoarse with much shouting.
W is for Whitby, renown'd for its jet;
X the policeman whom nothing could fret.
Y is for York and its int'resting "questions,"
Z is for Zoology, one of the "sections."

R. F. H.

THE ANCIENT LAND LAWS OF INDIA.

SIR,—Students of Sanscrit are unanimous that the ancient land laws of India are the oldest established on the globe. The royatwar, or individual settlement, by which the royatwar, or cultivator, pays rent for the farms he himself cultivates, and should they prove unproductive owing to a dry season he is entitled to an abatement, is a judicious mode by which the industrious are not made to support in indolence an idle portion of the community. A permanent royatwar is a fixed sum paid in all seasons for the farms the cultivator occupies. The landlord, accompanied by the taseldars, makes a personal inspection of the uncut crops, which enables him to judge where remissions should be afforded. That the Irish members, with all their eloquence and capacity for obstruction, should have omitted an uncut clause in the Irish Land Bill completely overwhelms me. It will be a good day for England when the students at Oxford, Cambridge, and the boys of St. Stephen's will learn more Sanscrit and less Greek. PIERSE ARTHUR.

CEMENT AND VEGETATION.

SIR,—I am about to plaster with Portland cement a house in Devon, surrounded by trees, many of which are close to it. I wish to throw sand against the cement before it has set, to give it colour and a rough appearance, but I am advised to finish off the cement smooth, lest the sand should promote the growth of vegetation in this damp climate. Others tell me that nothing ever grows on Portland cement.

The house stands on the top of a hill, above all damp from valleys, and in a dry situation apart from trees. My desire is to use the sand for the sake of appearance, but I shall be glad to hear what others say.

DEVON.

DEVELOPMENT OF THE COLOUR SENSE.

SIR,—The discussion upon this subject at the meeting of the British Association, I must confess, somewhat surprised me. The general conclusions of modern science are sometimes lost sight of in special studies. Thus colour in the paper referred to is regarded as an entity external to sense, which the eye either spontaneously perceives, or has to be developed to perceive; whereas, according to the received theory, colour, as colour, has no existence whatever, save and except as a mechanical vibration. Colour is a condition of the optic sense, coeval in all probability with the existence of an eye. We might as reasonably talk of the development of the sense of heat. From one simple point of view, indeed, namely, in the sensitiveness of nervous organisation to appreciate delicate variations in the modes of force, there may have probably been progressive development. The characteristics of what we term "culture," "refinement," are indications of a change towards higher nerve sensitiveness. Fondness for violent contrasts in sensation belongs to the barbaric state. There are eyes in animate being which possibly exceed the human in sensitiveness. Nerve development has probably a human limit, beyond which it can no farther go. To this goal is progression, and from it decadence. It would appear as if human nature itself, as all cosmical phenomena, were amenable to the eternal tidal action of ebb and flow.

METER.

SMOKY CHIMNEYS.

SIR,—In reply to a last week's correspondent, I beg to tell your readers that they may cure a great many smoky chimneys by the use of fine wire gauze in front of the fire-place, and that the success depends entirely on the gauze curtain approaching very nearly to the character of a "blower." The finer the mesh and the nearer the gauze-curtain is brought to the fire-bars, the more violent is the draught you get; but though in some or many cases a smoky chimney may be cured, a certain price has to be inexorably demanded for it and paid. The air which has passed away must and will be replaced. If it cannot be replaced by pure air, it will be replaced by foul.

EDDK. EDWARDS, JUN

Sir,—In lieu of a sheet iron blower, use fine wire gauge (that used for meat-safes), iron or brass, to suit the room, strained over an iron wire frame, and suspend by pins from the centre of the grate. The writer has used blowers of this description for the past thirty years, and there is nothing better. I think the *Builder* gave me the idea. EDW. COBFIELD.

A VIKING SHIP.

SIR,—Allow me to thank you for the excellent *resumé* you give, in your number of September 10th, of the paper I read before the British Association on the Viking ship. I trust it proves of interest to your readers. Though generally most correct, there are one or two errors, doubtless stenographic in origin, which I should not like perpetuated, and, therefore, may I ask you to kindly insert these lines?

Bow and stern are similar in shape and are *pointed*, not *painted*. This is an important fact, because the shields show signs of paint, but the timbers of the boat none. Then again, "In the Frithiof Saga, however, the 'ball of copper' was spoken of." This should of course be "keel of copper." Also "Starboard was a corruption of the word 'starboard,' which, no doubt, owed its origin to the ancient position of the rudder, as in this galley." *Starboard* should be *steerboard*. The vessel was excavated at Golestad.

The sepulchral chamber was tent-like in shape, made of logs placed side by side, leaning and meeting on a ridge-pole running parallel with the main axis of the ship. There is nothing about "the side running." The treaty made, at the end of the Vikings' descents on Scotland, was between Malcolm and King Sweno of Denmark.

J. HARRIS STONE, M.A.

TREATMENT OF CANDIDATES.

MIDDLESBROUGH AND STOCKTON BOARD.

AT the last ordinary meeting the Board proceeded to appoint a general manager for the waterworks, at a salary of 500*l.* a year. One hundred and nineteen applications had been received in reply to the Board's advertisement, many of the applicants having had extended experience in connexion with waterworks. Alderman Williams proposed Mr. D. D. Wilson, of Middlesbrough, a recently retired member of the Water Board, Mr. W. Jones seconding.

Mr. John Dunning proposed that the Board should choose out of the list of applicants three or four for consideration. He trusted they were not going to make a farce of the business in getting gentlemen to send in applications for the vacancy, if the applications were not entertained. Mr. D. D. Wilson had criticised the expenditure of the Board, but the members would now be able to see what he meant at.

Mr. Knowles (Stockton) seconded the amendment, saying he would be no party to a foregone conclusion.

Mr. Smith (Mayor of Stockton) thought they were acting dishonestly in the case of the gentlemen who had applied; some had even said that the appointment had been arranged beforehand.

Eventually, upon voting, Mr. D. D. Wilson was appointed by seven votes to two.

It was arranged to meet in a fortnight to draw up an agreement with Mr. Wilson.

IZAAK WALTON'S HOUSE.

THE block of houses between Bell-yard and Chancery-lane, facing Fleet-street, will shortly be demolished in order to widen the roadway in front. It is claimed that one of these houses was once the residence of the author of "The Compleat Angler, or Contemplative Man's Recreation." Peter Cunningham, in his "Handbook for London," vol. i., writes,—"Isaac Walton's house was about the seventh on the left-hand side as you walk from Fleet-street into Holborn. He lived here from 1627 to 1644." Thornbury, in "Old and New London," is more precise as regards the locality:—"Izaak Walton, that amiable old angler, lived for some years (1627 to 1644) of his happy and contented life in a house (No. 120) on the west side of Chancery-lane (Fleet-street end)." Certsin it is that, at two periods during his residence in London, Walton occupied a house in Fleet-street. A deed, bearing date 1624, in which year Walton was married, expressly describes Walton's abode to have been "on the north side of Fleet-street, in a house two doors west of the end of Chancery-lane, and abutting on a messuage known by the sign of the Harrow. The second period at which Walton was a resident in Fleet-street is shown by the parish register of St. Dunstan, Fleet-street,—"1633-4—March 21. Henry, son of Isaac Walton, was baptized, out of Fleet-street." The same register shows that in the previous year Walton resided in Chancery-lane:—"1632. —October 17. Henry, sonne of Isaak Walton, was buried, out of Chancery-lane." These entries refer, of course, to two different children, both of whom died in early infancy. It is well to preserve, as far as improvement will permit, any visible record that will recall "meek Walton's heavenly memory," as Wordsworth sings; but none such exist in Chancery-lane or Fleet-street. Walton's residence in the latter was pulled down in May, 1799, to widen the entrance in Chancery-lane, in which no vestige of what might have been the residence of the hosier-angler now exists,—even its position is a matter of doubt. Had either of the above houses existed in 1805-7 it would certainly have been noticed by "An Architect" who, during these years, contributed a long series of elaborate papers to the *Gentleman's Magazine* on the old houses of London, more especially those in Fleet-street and its neighbourhood.

STRATFORD-ON-AVON CHURCH.

THE LATE MR. HARVEY EGINTON.

SIR,—Your inquiry as to the drawings of Stratford-on-Avon Church restoration has just now reached me, as I am the only remaining relative of the late Mr. Harvey Eginton,—I am his sister. All drawings, &c., relative to Stratford and elsewhere became the property of his head clerk (Mr. Field), who shortly after went to Australia, and in about two years' time died suddenly in a street there. I do not know any of his relations or friends, so I fear you will fail to trace the information you require.

EMILY AUDLEY EGINTON.

CHURCH-BUILDING NEWS.

Micheldever.—The parish church of Micheldever, Hants, has been re-opened, after having undergone extensive alterations and restorations at the expense of the lay rector, the Right Hon. the Earl of Northbrook. It is reported that about the year 1806 the church was destroyed by fire, but nothing has been found during the progress of the work to corroborate this; at any rate, a few years afterwards the church was rebuilt by Sir Francis Baring, this being completed in the year 1810. It then remained without alteration (with the exception of a new east window to the memory of the late Lord Northbrook) up to the commencement of the present restoration. Up to this time the church consisted of a western tower (sixteenth century) massive and embattled; a nave in the form of an octagon, with two quasi-transepts (1810) built of red brick and covered with slate, and having heavy plaster arches and mouldings in its inside. The old chancel was covered with cement on the outside, and encumbered with very heavy plaster mouldings and arches inside. The seating was of oak, narrow and uncomfortable, and placed on a stone floor. The improvements consist of the entire restoration of the chancel; the insertion of a panelled and moulded wooden ceiling, richly coloured and gilt; a new chancel arch, with marble columns: a glass mosaic pavement; oak stalls, altar-table and prayer-desk; brass altar-railing and standards, marble credence; carved stone pulpit and new oak seating. A fine old stone arch of Early Perpendicular work has been brought to light and restored. The west window has been filled with stained glass, the gift of Mr. W. Gale, of Micheldever. The total cost, exclusive of its lectern and west window, is about 2,600*l.* which has been borne by the Earl of Northbrook. The work has been carried out under the superintendence of Messrs. John Colson & Son, architects, Winchester. The chancel contains many beautiful monuments to various members of the Baring family, by Flaxman, to which Lord Northbrook has added a marble monument by J. E. Boehm, A.R.A., to the memory of the late Mr. Thos. Baring, of Norman Court. During the progress of the work several fragments of earlier work were brought to light, viz., the remains of two marble fonts of Norman workmanship, pieces of Early English, Decorated, and Perpendicular work, being the remains of a large vaulted ceiling, and a stone screen or reredos of large dimensions. The latter had been decorated with colour and gold, showing that there existed at some time a church of more than ordinary pretensions on the spot.

Taunton.—The new Church of St. Andrew, Taunton, has been consecrated by the Bishop of Bath and Wells. It is erected at Rowbarton to supply the wants of a rapidly-increasing district, near the Great Western Railway Station. It is built of Westleigh stone, with Doulting stone dressings, the walls being lined internally with ornamental brickwork. It consists of a nave, 73 ft. by 18 ft.; north and south aisles, 73 ft. by 9 ft.; chancel, 27 ft. by 18 ft; north transept, 16 ft. by 9 ft.; entrance porch; and vestry. The tower forms the south transept, and is surmounted with a wooden spire covered with Westmorland slate, and is 100 ft. high to the weathercock. The nave arcade is carried on octagon brick piers, the arches being also of brick in colours. The roofs are open-timbered, covered with plain tiles and plastered between the rafters, except the chancel roof, which is boarded and decorated. The benches are open and of pitch pine, with moulded and framed ends. The passages and chancel are laid with Minton's tiles. The pulpit and font are of Beer stone. The east and south windows of the chancel, also the ten quatrefoil windows of the clearstory are filled with stained glass by Hardman. The church will seat about 500 persons, and the cost has been about 3,000*l.* It has been erected from the designs of Mr. J. Houghton Spencer, of Taunton; the builder being Mr. H. J. Spiller, also of Taunton.

Brynamman.—The Bishop of St. David's has consecrated the new church which has been erected at Brynamman for the accommodation of the 200 persons who, some two or more years back, severed themselves from the Welsh Congregationalists' communion in order to join the church of their forefathers. The building will accommodate 300 persons. It consists of nave, 55 ft. long by 25 ft. wide; and chancel, 26 ft. long by 16 ft. wide. The latter has a small aisle on the south side, and the former a baptistery against the west wall next to a double porch, while on the north side of the chancel a commodious vestry with fuel chamber beneath is provided. The walls are substantially built in courses with dark grey local stone, relieved by windows and dressings of Westwood stone, and the roofs are covered with light grey slates from the Whitland Abbey quarry. The interior, which is well lighted by twelve tracery-headed windows and ten lancets, has lofty side walls and high-pitched roofs, giving a total height of 36 ft. in the nave. The chancel has a boarded ceiling. The pulpit, lectern, stalls, and seats generally are all of pitch pine, the latter fixed upon raised wooden platforms, while the pavements consist of a mixture of stone flagging and Webb's (Worcester) encaustic tiles in patterns. The altar standards were made by Mr. T. Brawn, of Birmingham, in wrought iron and brass work, and the stone carving has been well executed by Mr. Clark, of Hereford. Ample means both for warming and ventilating have been provided, one of Porritt's underground stoves, with flue running the whole length of the nave, being introduced for the former purpose. The whole outlay has not exceeded the original estimate of 1,500*l.* The contractors were Messrs. Balcombe & Price, of Pembroke Dock. Mr. Hay, of Brynamman, acted as clerk of works, under the general direction of the architect, Mr. E. H. Lingen Barker, of Hereford.

St. Breock (Cornwall).—After undergoing restoration, the parish church of St. Breock, near Wadebridge, has been re-opened. The church, which consists of a nave, chancel, south aisle, two little transepts, and a tower, was erected in the sixteenth century. Some time since, owing to the dilapidated state of the church, consequent on the dampness of the situation, it was found necessary to have the building restored. It was resolved, after a while, to have the church renovated, and Mr. J. Piers St. Aubyn was appointed the architect, and the contract was let to Mr. Searle, of St. Austell. The walls, although they have not been rebuilt, have had to be thoroughly renewed,—pointed outside and plastered inside. The church has been thoroughly drained and reseated, open benches of pitch-pine taking the place of the old square pews, and the floor-spaces in the chancel have been covered with tiles, supplied by Mr. Godwin, of Lugwardine, Hereford. The stonework of the arcade has been cleaned, and a stone archway has been made to the two transepts. The roof has been thoroughly repaired, the old wagon-headed shape being retained, with carved bosses by Mr. Webber, of Bodmin. The windows have been reglazed by Messrs. Fouracre & Watson, of Stonehouse. The cost of the restoration is estimated to be 1,400*l.*, and the work has been carried out under the superintendence of Mr. Collins, of Wadebridge, the clerk of the works.

Liverpool.—The foundation-stone of the new church of St. Stephen the Martyr, Liverpool, has been laid by the bishop of the diocese. The church, which originally stood in Crown-street, was taken down owing to the opening up of the tunnel from Lime-street to Edge-hill, and is now being rebuilt, stone for stone as before, on a new and eligible site at the angle formed by the juncture of Crown-street and Grove-street. Great pains have been taken to find the original foundation-stone, of which no information could be obtained, and it was not until the whole church had been taken down that the stone was discovered. On this account the building has been considerably advanced without any attempt at a stone-laying. The long-sought stone having been found, it was decided by the incumbent, the Rev. E. P. Hodgins, D.D., to have it re-laid. The church has been taken down owing to the opening up of the tunnel by the London and North-Western Railway Company, and is being rebuilt on the lines of the original church, as designed by the late Sir Gilbert Scott, under the direction of Messrs. Thomas D. Barry & Son, architects, Liverpool. Mr. John Miller, of Liverpool, is the builder, Mr. Peter Thomas being the clerk of the works.

SCHOOL BUILDING NEWS.

York.—The memorial stone of a new wing to the Industrial Boys' Schools, Mary-gate, York, was laid on the 6th inst. by the Dean of York. The wing will cost 800*l.* The architect is Mr. De Maine, the contractor being Mr. Dennison.

Glossop.—A new school in connexion with Littlemoor Chapel, Glossop, has been opened. The structure now completed is a portion only of a larger scheme, which includes a range of class-room two stories in height, to be built hereafter in the rear of, and connected with, the present school-room. When that extension is added, the partitions now enclosing the two stories of six class-rooms at the east end of the school-room or assembly-hall will be removed. The height of the hall is 34 ft.; viz., 24 ft. to the wall-plate, and 9 ft. in the roof with sloping sides. The floor area of the hall, including the eastern class-rooms, will accommodate 550 adults seated at a lecture or concert. The gallery, which extends along each side, and at the western end of the hall, and is two seats in depth, will accommodate 200 adults, also seated. The three western class-rooms have fixed seats on raised platforms, which are practically a continuation of the gallery. These will accommodate 150 adults. The total capacity of the hall is thus for 900 adults comfortably seated, besides the occupants of a speaker's platform or orchestra. The principal elevation, or front of the building, is towards Victoria-street, which is on the high road from Glossop to Hayfield. This street rises considerably, and the site also rises still more rapidly from front to rear. At the south-west angle of the front a turret, nearly 12 ft. square, is placed, which rises to a height of 75 ft. from the ground to the top of the vane. Turning to the left, after

passing through the porch, a spacious lecture-room is entered. This apartment is 36 ft. long, 20 ft. wide, and 15 ft. high, and is well lighted by front and end windows. In the north-west corner is a lift from the basement chamber, where the tea-boiler is fixed; and immediately opposite are steps up to a service doorway which opens into the assembly-hall. (The floor of the hall is 5 ft. above the lecture-room floor.) There is also a gallery for 100 infants, which is so constructed as to be readily taken apart and put together again. The steps are also movable, and these and the infants' gallery can be stowed away in a chamber provided for the purpose underneath the assembly-hall floor. Native rubble stone has been used for the walls throughout; those towards Victoria-street and the chapel burial-ground (north) being faced with pitch-faced wall-stones from local quarries. All the block stone for the dressings is also from local quarries, and some red stone from Runcorn has been introduced. The roofs are covered with slate, and all the internal woodwork is of pitch-pine, varnished. For warming the building throughout Gibbs's system of hot-water pipes has been adopted. The style is Italian Gothic. A contract was entered into with Mr. Aaron Haughton, of Godley, for the whole of the work, at 2,570*l.*, his manager and foreman on the building being Mr. F. Wilson. The architects of the building were Messrs. Paull & Bonella. The total cost, inclusive of movable fittings or furniture, and play-ground and fences, architects' commission, and payment to clerk of works, is about 2,880*l.*

Rhyl.—Christ Church British Schools, Rhyl, have been completed and opened. They occupy a site at the corner of Crescent-road and Vaughan-street, including altogether some 1,200 yards of land, and are arranged as follows:—The ground-floor is prepared for the use of girls and infants, with entrance from Vaughan-street; the upper floor for boys, or mixed school, as may be determined upon, there being a total accommodation for at least 800 children, should the whole premises be used for teaching purposes. The infants' school is 32 ft. by 25 ft., with a large bay window in one side, and an open-timbered roof. A special room for babies is provided, 18 ft. by 15 ft. The girls' schoolroom is 90 ft. long and 22 ft. wide, and has large windows all down one side, kept well up from the floor, and going close up to the ceiling. A class-room, 27 ft. by 22 ft., is entered from the side of this room, and two others from the end, respectively 24 ft. by 22 ft. and 22 ft. by 16 ft.; stairs for communication with the mixed schoolroom over, and closets for books, &c., being provided between these class-rooms. The boys (or mixed) schoolrooms, &c., are on the first-floor, with entrance from the play-ground at the back, and private communication as before with the girls' rooms below. The large schoolroom is 60 ft. by 22 ft., with lofty open-timber roof, windows all down one side and one end, the other end having two large class-rooms, respectively 24 ft. by 22 ft. and 22 ft. by 16 ft., separated from the large room by sliding screens of pitch pine and glass, so as to be thrown into the large schoolroom or used separately as may be desired. Three other class-rooms are also provided, of somewhat similar dimensions to those named, with book-rooms, &c. The exterior is in brick and terra-cotta work. The architect is Mr. C. O. Ellison, of Liverpool. Messrs. Collin & Son, Warrington, were the general contractors, and Mr. Hammond has been clerk of works.

The Royal Polytechnic Institution finally closed its doors as a place of scientific amusement, if we may so term it, on Saturday last, having had a career of more than forty years. It had for some time ceased to be a remunerative concern to the shareholders. When it had been in existence ten or twelve years a rival to it, known as the "Royal Panopticon," Leicester-square, was projected and started, but the career of this latter venture was very short, the building (specially erected for it from designs by Mr. T. Hayter Lewis) having been for the last twenty years and more known as the "Alhambra." The Polytechnic was established before the days of Crystal Palaces and Great Exhibitions, and has fulfilled a useful function. Now its career is closed its promoters may congratulate themselves in remembering that many of its best features have been imitated by other institutions. There is no denying that it had become very dull and very dusty.

Miscellanea.

Burning of the Park Theatre, Camden Town.—The Park Theatre at Camden-town was totally destroyed by fire early on Sunday morning last. The theatre, which was originally known as "The Alexandra," and was erected some nine or ten years ago from designs by the late Mr. H. C. Robinson, who held the appointment of Architect to the Department of the Lord Chamberlain, was situated at the eastern end of Park street, Camden-town. The performances on Saturday night terminated about a quarter past eleven o'clock, when it was supposed that the gas had been properly turned off, that the theatre was closed, and that all the *employés* had left the premises. A few minutes before twelve a police constable observed smoke issued from the stage end of the building. He at once raised an alarm, and, in company with another constable, rushed into the stage entrance. To their astonishment they found a number of the actors and actresses, who had been engaged in the performance, packing up their dresses and properties in the lower part of the building. They had observed a smell of smoke, but were not aware that the place was on fire. The fire seems to have originated in the upper portion of the stage, probably in or near one of the dressing-rooms. Scarcely had the discovery of the smoke been made when flames burst out. The firemen directed their efforts to confining the fire within the building, and, in consequence of good outer walls and of the body of water thrown on the fire, by about one o'clock it was felt that this object had been attained, but it was not until between four and five o'clock on Sunday morning that it was finally got under, by which time the entire theatre was gutted. The old story; and yet in this case the existence of the fire appears to have been discovered even before the appearance of flames.

Manchester Royal Institution. — The negotiations for the transfer of this institution of the fine arts to the Manchester Corporation have been concluded on the eve of the opening of the annual autumn exhibition of pictures. The proposal of the governors or proprietors of the institution, about 350 in number, was to hand over their land and building in Mosley-street, with its pictures and statuary, to the municipal body, free of all cost but the payment of chief rent (about 100*l.* a year), and a guaranteed endowment from the city rates of 2,000*l.* a year for the purchase of pictures to enrich the permanent collection. This offer was agreed to by a committee of the corporation on the understanding that the endowment should be limited to the next twenty years, anything contributed after that to depend upon the public opinion of the time. The proprietors will hold one-third of the seats on the future committee of management, and their individual privileges of admission to exhibitions or lectures will be preserved. The art-gallery will be open free to the public on such days of the week as the committee shall determine. All proceedings of the governing body are to be submitted to the civic council for confirmation, as provided by the Municipal Acts. The building thus acquired by the public was erected from the designs of the late Sir C. Barry.

The New Town Hall at Staines has been opened. It has been erected from the designs of Mr. J. Johnson, architect, London, whose plans were chosen out of forty-five sets submitted in competition. The contract price for the hall was 4,797*l.* The building contains two assembly-rooms, one capable of containing 500 seats, and another about 250, whilst there are offices for clerk, surveyor, &c. At the top of the building are five rooms for the hall-keeper, and two kitchens in the rear. There are also ante-rooms, cellarage, lavatories, &c. At the rear of the building will be an ornamental garden with river-wall and promenade, an access from the Themes by a set of steps being also contemplated.

Mr. D'Oyly Carte's New "Savoy" Theatre will be opened at the end of the month, with "Patience," for which new scenery has been painted. The whole of the interior fittings, plastic work, upholstery, &c., have been designed and carried out by Messrs. Collinson & Lock.

Oxford High School for Boys.—The new High School for boys, erected in George-street, from the plans of Mr. T. G. Jackson, M.A., architect, the foundation-stone of which was laid by Prince Leopold some time since, was opened by the Earl of Jersey on Thursday, the 15th inst.

Sanitary Dwellings.—A meeting was held on Saturday, under the auspices of the Local Rights Association, in the hall of the club, Rose-street, Soho, to consider the question of unsanitary dwellings, and hear a statement of the objects of the association. Mr. Alfred Byrnes presided. Mr. Edwin Dunn explained that the association had its origin in an attempt by a few working men to do something to prevent their fellow-beings growing up in the wretched condition in which they were constantly found in the quarters inhabited by the working classes. They found the Artisans and Labourers' Dwellings Acts almost a dead letter or worse, because their working caused increased miseries to the parties they were meant to benefit. They had set about exposing some of the worst cases, and pointing out what they considered a remedy, viz, that the authorities should themselves build houses for the people, and let them to the labouring classes only at the lowest rental consistent with a fair return for money expended. Exorbitant rents were the curse of the working classes, and it drove working people into the lowest slums. The association also sought the abolition of distraint for rent, with a substitution of the County Court process. Those objects, he believed, entitled them to support. Mr. Beattie, Mr. Tranmere, and Mr. Lords, also addressed the meeting, and a resolution expressing approval of its objects was unanimously carried.

Dr. George C. M. Birdwood, C.S.I., of the Indian Museum, upon whom it is stated her Majesty has been graciously pleased to confer the honour of knighthood, is the second son of General Christopher Birdwood, of the Bombay Army, and was born in 1832. After serving for many years on the Bombay Medical Staff, he was appointed special assistant in the Revenue, Statistics, and Commercial Department of the India Office, where he has had special charge of the Indian Museum, and has rendered valuable assistance in examining and reporting upon the stores of Indian curiosities and works of art contained therein. He has also written a hand-book on Indian industries, and has commented largely upon Indian literature and philology.

Proposed International Exhibition at Manchester in 1882.—A proposition for the holding of an international exhibition at Manchester in 1882 has been mooted. It is suggested that the interval of twenty years since the last great exhibition of arts and industry in London is long enough for such changes and progress to have been made as must justify an exposition of them in England, and that Manchester might fairly be the place for it, as being the centre of a more populous district than any other,—a district with greater variety of productions and manufactures than any other, and easy of access by way of Liverpool to the most distant parts of the world.

Statistics of Wesleyan Chapel Building. The minutes of the 138th annual conference of the British Wesleyan Church, recently held in Liverpool, have been issued. From them we learn that erections have been sanctioned as under:—94 churches, at an estimated cost of 161,963*l.*; 9 manses, at 7,695*l.*; 10 school-rooms, at 4,531*l.*; 83 alterations and enlargements, at 41,563*l.*; 99 modifications, at 35,975*l.*; 26 organs, at 7,549*l.* The following erections have been completed during the year:—141 churches, costing 229,912*l.*; 13 manses, 13,205*l.*; 26 school-rooms, 12,324*l.*; 89 alterations and enlargements, 55,687*l.*; 14 organs, 5,326*l.*

Kendal.—It is proposed to reseat and decorate the Unitarian Chapel, Kendal. The ceiling will be panelled and ornamented in plaster, the seats will be of pitch-pine. There is also to be a new organ. The cost of the works, including organ, will be about 1,000*l.* Mr. Eli Cox is the architect.

Liquid Chinese Ink.—We have received a bottle of Wolff & Son's Liquid Chinese Ink. It appears to work well, and does not wash up when once dry. Whether it would retain this quality when stale would have to be seen. For pen-and-ink drawing the liquid ink is obviously convenient.

Readle's Glazing.—By some unaccountable accident in the composing-room, the Citadel Station at Carlisle, represented in Messrs. Readle & Co.'s advertisement last week, and which is glazed on Readle's Patent System, is described as at Glasgow. It is rightly allocated in the paragraph we gave in the same number announcing the lamented death of the patentee, but we think it right to point out the slip. The work is an important one.

Unsafe Letter-Boxes.—The *Northampton Herald* records a bank robbery by children at Wellingborough. It seems that on a recent Sunday morning, two little boys named Walter Weaver and Frank Blunt, both under seven years of age, were playing against the Union Bank, in Market-street. One of them put his arm down the Bank letter-box, and reached out a letter containing 1,400*l.* in cheques, which had been paid in at Northampton on Saturday, and were of no value to anybody except the Banking Company. The young urchins then proceeded to give away the cheques, putting some under shop-doors, and otherwise distributing them. Sometime on the Monday the matter came to the ears of the police, and the delinquents were questioned, and inquiries made about the missing cheques, and most of them were speedily recovered. The building has been erected about a year. Unless we are mistaken, Messrs. Hart, Son, Peard, & Co., a few years since introduced a patent letter-box ("Shove's patent," we think it was called) intended to prevent the abstraction of letters. The incident mentioned by the Northampton paper shows the importance of attending to what is apparently a small detail in a building. Where it is necessary to make the slit or entrance to the letter-box large and wide, for the admission of newspapers and book-packets, the box should be made sufficiently large and deep as to place its contents beyond the reach of pilfering fingers.

"Dover Priory Gateway."—With reference to the paragraph in our last, thus headed, we have received a letter from a solicitor, on the part of the gentleman who has, it is said, hitherto acted as architect for the college, stating that it "reflects upon him in his profession," and demanding an apology for its insertion. Having committed no fault we can scarcely apologise, but we shall be very sorry indeed if the paragraph be misunderstood. There was no intention to "reflect," in the slightest degree, upon any one. The sole intention of the paragraph, hastily written at the last moment, was to decline entering into a discussion, concerning the merits of which we know literally nothing. Expediency, mere personal preference, in fact any one of half a dozen reasons, none of them reflecting on the professional character of the local architect, might be quoted by the Council as sufficient to justify them in changing, and it was to such as these we referred. At the same time, for anything we know, the Council may be utterly in the wrong.

What might have been expected.—The *Times* of the 9th inst. describes an accident which occurred on the previous day at Yarmouth to a youth named Sidney Plucknett, in the employment of Mr. Salter, contractor. The head of the smith department was cleaning an ordinary iron oil-drum, and placed it, containing some water tightly corked down with a wooden plug, on the forge fire, with instructions to Plucknett to make it boil. The generated steam having no escape, a terrific explosion resulted, which wrecked the shop and threw the boiling water over the youth's chest and face, inflicting severe injuries, from which he died in three hours.

Bunhill-row.—Great changes are taking place in this locality. Nearly all the dwellings on the right hand side as far as the church of St. Paul are being demolished, the leases having fallen in. The ground has been let upon a building lease to Mr. Walker, of Bunhill-row, by the Hon. Artillery Company.

At the Royal Manchester and Liverpool Agricultural Society's Show, held at Blackburn on the 1st, 2nd, and 3rd of September, Messrs. W. H. Bailey & Co., of the Albion Works, Salford, exhibited their slow-combustion hot-air engine, and obtained the first-class silver medal for its excellence.

Glasgow Institute of Fine Arts.—The galleries of this Institute in Sauchiehall-street are now open with an exhibition of works in Black and White (1,127 in number), in addition to the works exhibited by the Scottish Society of Painters in Water-Colours. Both departments of the exhibition are well worth visiting.

Cost of the National Museum, Amsterdam.—The amount of the various contracts given in our account of this building (p. 295, *ante*), was in guilders (1*s.* 8*d.*), not francs, as we were informed and stated.

An Exhibition of Irish Industries is proposed to be held in Dublin next year. The promoters feel assured of success, and the guarantee fund is assuming large dimensions.

Scarborough.—New "Barracks" (by which they mean a chapel or meeting-house) are being erected here for the body known as the "Salvation Army," and the foundation-stones were laid on the 30th of August. The "barracks" will occupy a site at the junction of Almaparade and Victoria-road, and are intended to accommodate 2,000 "soldiers," in other words, a congregation of 2,000 persons, men, women, and children.

Margate.—The Roman Catholic Church of St. Vincent, in the Victoria-road, Margate, was recently reopened. From the designs of Messrs. Pugin a new pitch-pine roof has been added to the church by Messrs. Brown & Son, and the sanctuary,—indeed, the whole church,—has been re-decorated, the cost being 300*l.*

The Arts' Association Exhibition, Newcastle.—Of the 774 pictures and drawings exhibited this year, nearly 200 are by local artists. Taking into account that no one can send more than three works, this represents a large number of exhibitors.

Trade Unions Congress.—The Congress of Delegates was opened on Monday last in St. Andrew's Hall, Newman-street, Oxford-street. Many topics have been dealt with, and shall have our attention next week.

Wandsworth Public Hall.—The right title of the firm who supplied and fixed the heating apparatus here is "The Thames Bank Iron Company."

TENDERS

For the erection of shops and premises, North Cross-street, Gosport, for Mr. Bishop. Mr. Jas. W. Stroud, architect. Quantities by Mr. C. M. Houghton:—

The Word "Nature" in Reference to Art.

CORRESPONDENT recently drew attention in our columns, not without reason, to the confusion of thought arising from the varying senses in which the word "nature" was used in art-criticism. Another correspondent, Mr. J. K. Colling, in a letter printed in a previous number, took some exception to our criticism of his introduction to a book on design, in which we suggested that he had pushed too far the statement that all ornament must be founded on geometrical forms. In his letter Mr. Colling said that such forms were based upon nature, and that "all mathematics and geometry are closely allied to laws which exist in nature."

It was to this sentence especially that our second correspondent, Mr. Cave Thomas, took exception, and thereupon demanded that people should settle what they mean by "nature" when they refer to it as the basis of art. Without going so far as to say that no discussion on any artistic topic is of any value until people have settled what they mean by "nature," we must at least say that the word has been used with great laxity and vagueness as to its meaning, and that our correspondent did usefully in calling attention to the point, even though, as it appears to us, he showed that he himself was under a certain confusion, if not of perception, at least of expression, in regard to it, though by no means so much so as the first correspondent whose expression he criticised. To say that mathematics and geometry "are closely allied to laws which exist in nature," is, in fact, a most extraordinary confusion of terms; Mr. Colling may pardon us for saying so, since it has been his business to express himself with the pencil rather than with the pen, and we do not take his laxity of literary expression as in any way invalidating the value of his artistic taste, feeling, and draughtsmanship. Taking the word "nature" in the widest sense, mathematical and geometrical facts are not merely "allied to" nature, they are the expressions of laws which exist in nature. But Mr. Colling did not mean to use the word "nature" in its widest sense. What his sentence evidently meant, if it had been less vaguely expressed, was that the relations between lines and surfaces which exist in geometry and are demonstrable by mathematics, are frequently illustrated in the facts of external nature; the word "nature" being here used as expressing the aggregate of the external forms of nature, organic and inorganic.

The confusion of idea, and it is one which we admit is constantly recurring, is between outward forms of natural production, and what are regarded as principles or laws governing everything in nature, and among other things governing, more or less, the formation of vegetable growths, which are the basis of a large proportion of ornamental design. In fact, if we closely examine the point, we shall see that the one word "nature" is used in three different meanings when nature is spoken of as the basis of art. We may say that the disposition of lines and spaces is pleasing in proportion as they adhere to certain geometrical forms which have their basis in natural law. That is one use of the term, and that refers entirely to abstract laws which are capable of demonstration by pure theory and apart from any artistic representation at all. We may say, again, it is a law of nature that trees and plants should give forth branches at nearly regular intervals and at different sides of the central stem in succession; that is a fact referring to the mechanism of the plant, and also capable of statement without artistic illustration, but it is not, like the previous class, a law affecting all our conceptions of spaces and proportions in whatever material; it is a fact habitual to a certain class of natural growths. Then the third sense is when we see a drawing, say of a leaf, supposed to represent a specified leaf in nature, and we say "that is not correct, not according to nature, the natural shape is this," and then comes in the aid of the pencil, without which in this case we cannot make ourselves intelligible. This third use of the word refers to isolated facts and forms in nature, which we are supposed to be imitating, so that here the connexion between "nature" and "art" is the most obvious and immediate of all.

Now it is hardly possible in this case to settle what we mean by "nature," that is, to attach the word to one only of those meanings, unless we are willing to leave the other meanings without a word to express them, or else to agree to the use of some modifying expression which will indicate in what sense we mean to refer to nature. Now it appears to us that this modifying expression may be supplied by two words, one of which has got a rather bad name through being constantly used in reference to what are supposed to be vague and dreamy speculations; but which are in reality perfectly logical and intelligible expressions, calculated, when rightly used, to save a great many words and a great deal of misunderstanding (we mean "misunderstanding" in the direct, not in the secondary sense). These are the expressions "physical" and "metaphysical," of which the former of course is nearly the Greek equivalent of "natural," — entirely the equivalent in its accepted meaning; and the latter is one of those convenient combinations which the pliant Greek language was so well able to frame to express a complicated meaning in one word. If we were to invent a corresponding expression to go with our word "nature," we should say that "natural" and "sub-natural" would be the equivalents; but we do not think that good fortune attends upon attempts deliberately made to invent new words. Going back to the old Greek compounds, therefore, which have long been adopted into our language, we know that the simple word "φύσις" is the equivalent of "nature," external nature, the garment of the world; physical is "natural," physical facts are facts in nature, physical laws are laws of nature, —outward visible nature, be it observed. Then that which is metaphysical is—what? That which is behind nature, that which we come to when we endeavour to penetrate below the physical facts to any laws or what we may call in one sense facts which are not physical, but are capable of demonstration quite apart from external nature. To give one illustration, it is a physical fact that bees make their cells hexagon shape; it is a metaphysical fact that the hexagon shape allows of contact on all sides without any loss of space; *meta*physical, because that property or capability of hexagons would be the same in any material and under any circumstances, and would equally exist if all external nature were swept away, and would be capable of demonstration in figures without any reference to external nature at all.

Let us see how this applies to the subject in hand. It is asserted by the advocates of symmetrical and geometrical arrangement in ornamental design, that such arrangement largely, if not entirely, pervades "nature," by which term some of them mean apparently that geometrical symmetry is based on natural laws, and that, therefore, geometrical ornament is "founded on nature"; others assert that a minute inspection of nature will reveal a constant or almost universal presence of geometrical and symmetrical forms. Among the upholders of this latter view was Owen Jones, who, to our thinking, greatly overstated his position. Nor can we accept Mr. Cave Thomas's way of putting it in his letter in the *Builder* of the 3rd inst., that "regularity and irregularity are two extremes, between which nature, art included, is always striving to steer a middle course." That is a very empirical way of stating the case. Our belief is that all symmetry in the organic forms of nature is mechanical in its origin; that it occurs or originates at least where there is some advantage to the organism to be gained by it. Take the spiral growth of trees and plants, which put out their shoots at opposite sides alternately. A tree which put out all its branches at one side would be under the double disadvantage of being liable to be pulled over on that side by its weight, and of breathing the air from one quarter only instead of from all sides. Animals are bi-symmetrical because this formation is necessary to their balance and to the alternate

movement required for progression, and in their case a considerable exactitude of symmetrical arrangement is necessary to their comfortable existence. Leaves are bi-symmetrical mostly, apparently, because this is the best way of securing equal radiation of sap from the central stalk; but their symmetry has much more latitude than in the case of animals, as has that of the whole plant also, in the great majority of species. Anything like absolutely geometrical symmetry is, in fact, the exception in the forms of the vegetable kingdom, and in the animal kingdom even is only to be found in the main disposition, not in the details. The hands are symmetrically disposed; but the hand itself is quite unsymmetrical. Almost the only instances of absolute geometrical symmetry in nature are in some inorganic products, such as snow crystals, and these are in quite a different category. These do not, as far as we understand them, arise from any such "survival of the fittest," as that which we may suppose to have developed the symmetrical growth of plants on either side of a centre; they are simply the results of all-pervading laws of arrangement and balance of matter, acting upon very impressible and fragile materials, and kneading them into shapes accordingly. They are the effect of a law of nature, in the same sense that the circular ripples from the splash of a stone in water are the effect of a law, with the difference that the latter effect, in a fluid material, is evanescent; the former is durable.

Those, then, who defend symmetry in ornament on the ground of the existence of symmetry in physical organic forms, rest on a false footing. Such symmetry as we exhibit in designing symmetrical ornament has very little existence in nature. The true meaning of symmetrical ornament, exhibiting or founded on natural forms, more or less conventionalised, is that, in designing it, we take details from physical forms, and combine them in subordination to broader metaphysical laws, or perhaps only to a broader and more typical reading of the physical law. The physical law that plants should sprout on alternate sides of the stem, for example, may be generalised into a form representing the completely symmetrical giving off of lines on either side of a centre, expressing the general idea of the plant growth, although the same mathematical symmetry would not be found in any individual plant. In this case, from the physical fact, we generalise metaphysically to an artistic expression of the principle.

When we come, therefore, to the question whether ornament ought to be symmetrical or not, it is not so much a question of what is according to nature or not, as of the way in which you choose to use nature, and the view which you take as to the object of your design. Taking the question which gave rise to the letters that suggested these remarks, as to how far we should recognise or approve the unsymmetrical ornament of the Japanese, we have no hesitation in saying that much of the more symmetrical ornament of Classic, Arabian, and Mediæval times, is a higher stamp of work, because more thought goes to the production of it, —that it is a treatment of forms based on physical facts in accordance with the application of metaphysical laws or ideas; whereas the Japanese is simply the imitation of the natural facts without the application to their treatment of any higher law. We suspect the fact is that to the Japanese artist, what we call his ornamental design is not, in his mind, ornament at all, in the sense in which we use the word, but painting from nature; an art which, it is needless to say, stands on quite a different ground from ornamental design. In some other forms of ornamental design, which have by one writer been called "abstract ornament," such as the Greek fret, and the Arabic interlacing patterns, the basis of the design is purely metaphysical, that is, it is a kind of playing with geometrical laws and proportions, which are quite apart from external nature, and weaving a kind of physical growth of our own designing on the basis of them. Just as there are three ways of regarding nature as the basis of ornamental design, so there may be said to be three methods of producing ornamental design; that in which we follow laws of pure geometric proportion, and illustrate them in a more or less playful way; that in which we adopt physical forms, but subject them to metaphysical laws in grouping and arrangement; and that in which we simply reproduce physical forms. Of this latter, of which, of course, the greater part of Japanese ornament is an illustration, it is an open question, strictly speaking, whether it ought to be called ornament at all, and whether it was ever intended so, in one sense, by its producers: but it is at present called so.

When, therefore, to conclude, any one raises the question whether ornament should be an imitation of nature or not, or whether such-and-such features in it are in accordance with nature or not, what we have to do, before it is any use arguing further with him, is to elicit from him whether he means according to *metaphysical laws* of nature, or *physical laws*, or *physical facts*. That is the essence of the question he has to answer. If any one can suggest a better nomenclature to put it in we shall be very glad to hear it.

A TIDAL PORT FOR LONDON.

IT was a not unusual remark, some thirty or forty years ago, that the Thames was the finest dock in England. Indeed, a strong, if blind, patriotism often went so far as to call it the finest dock in the world. The remark showed, indeed, that the man who made it had never seen Milford Haven, Falmouth, or Cork Harbour. But the fact that the shelter and facility which the Thames affords for shipping have been the making of London is beyond doubt. And if the words "the most frequented port" were substituted for those which we have quoted, there could be no ground to quarrel with their exactitude.

With the immense growth of the steam navy of the world, a growth not only in the numbers but in the size of the vessels, the disadvantages of berthing in a tide way, instead of steaming into a tidal dock, are becoming year by year more apparent. And, notwithstanding the growth of those noble docks that already line the banks of the Thames, there is still much to be desired in the way of providing a port into which vessels may enter, and from which they may depart, at any hour of the day, or at all events at each flood tide. Even the most capacious of the docks now existing alongside of the Thames are inadequate for the reception of the largest steamers now afloat. There is no dock, it is stated, into which the *Orient*, the *City of Rome*, or other steamers of the same class, can at present enter. And even vessels of somewhat less draught cannot be docked in a single tide; as by the time the ship comes up from the sea in the twelve hours for which the tide serves, the water has sunk to too low a level to float the vessel over the cill of the dock. Thus twelve or even twenty-four hours are lost, as great ships invariably anchor off Gravesend for twelve hours to await the following tide.

On entering the river Thames, the broad open channel called Sea Reach runs for ten miles nearly due west, after passing Yantlet Creek. It then bends to the south, the bend forming Lower Hope Reach, which is about four miles long, or from three to three and a half in the fair way of the channel; and then again runs westward for about five miles, through Gravesend Reach. About the middle of this reach lies the town of Gravesend on the south, and Tilbury Fort on the north of the river. It is here that the principal ocean-carrying companies now for the most part embark and disembark their passengers, communication with London being kept up by the North Kent Railway on the right bank of the river, and by the London, Tilbury, and Southend Railway on the left bank. From Yantlet Creek to London Bridge is forty-one miles by the river; and it is forty-eight miles from the Great Nore, below the junction of the Medway, to the Bridge. Gravesend is by river twenty-seven miles from London Bridge, through which distance the course of the river is tortuous, with lessening depth and narrowing width. And such is the peculiar character of the river, and such the force of the winds, tides, and currents, that low water in London is sometimes actually lower than low water at Sheerness. On the 24th December, 1877, it is stated by Mr. Redman, C.E., to whom the Thames has long been a subject of attentive study, the low water at London was 4 ft. 4 in. lower than at Sheerness. The depth of water between Tilbury and Gravesend is from 40 ft. to 50 ft. at low water. The range of the tide is from 16 ft. 10 in. to 17 ft. 6 in. at Sheerness, and from 20 ft. to 22 ft. at London.

The directors of the East and West India Docks have now purchased an area of 450 acres on the left bank of the river Thames at Tilbury End, opposite Gravesend, with the purpose of there constructing great docks, capable of receiving the largest vessels now built at any time of the tide. A tidal basin of sixteen acres in extent, and 40 ft. deep, will open by an entrance 200 ft. wide into the river. From this basin access will be given to the docks by a lock of 700 ft. long, with a depth of 40 ft. water on the cill. The floating docks are to have a quayage of 15,000 ft., allowing working berths to thirty steamers of 400 ft. each in length. There is to be a dry dock of 825 ft. in length, as well as others of less colossal proportions. All modern appliances (in which the Americans are probably far ahead of ourselves), in the way of elevators, coaling lifts, and the like, will be provided, with hydraulic power, such as we recently mentioned as applied to the new docks at Liverpool. Landing stages will be provided for the embarkation and disembarkation of passengers at any time of the tide. Pilotage, tugging, risk of fogs, risk of collisions, delay in warping up twenty miles of winding channel, will all be avoided by this opening of a new front door for the maritime commerce of London.

The one point which strikes us with wonder on comparing the outline of this project with the chart of the River Thames is,—"How is it that this scheme has not long ago been taken in hand?" Floating or wet docks were first introduced at Liverpool about the year 1716. They have since that time been introduced into almost all the principal ports of the kingdom. In the Thames the East and West India Docks were constructed by Jessop, Rennie, and Ralph Walker; the London Docks, by Rennie; the St. Katharine's Docks, by Telford. Much has been spent in providing the accommodation that now exists. Mr. Robert Stephenson and Mr. Bidder, when they commenced, almost at their own risk, the railway to Tilbury, must have had some not indistinct idea of the manner in which railway communication would react upon river communication, as regards the position of a sea-going station. The whole line of river shore from Stanford-le-Marsh to Coal House Point, and thence to Tilburyness, seems as if it had been especially provided by nature for the construction of floating docks. From any part of London it may be made as easy to get to Tilbury as it is now to get to Blackwall. The addition of some sixteen miles to the railway journey is as nothing when compared to the saving of from twelve to twenty-four hours in clearing the Thames after embarkation, and when we regard what is even more important than gain of time, namely, certain punctuality of departure, and, to an increased extent as compared with previous conditions, punctuality in arrival. The estimate which is mentioned of 1,100,000*l.* seems to us very inadequate to such an enterprise as is now foreshadowed, especially when we recall the sums expended on the docks at Liverpool. We trust that no false idea of economy may be allowed to mar the execution of a scheme which we take to be one of the most important, as well as one of the most promising, of which we have recently heard.

In saying this, however, we confine ourselves to the approval of the principle of the design, as far as concerns the construction of docks at Tilbury. As to the details, we are as yet unaware of more than we have previously stated. We should not feel called on even to make this reservation were it not for what seems to us the small sum named as the cost. Of course, if land enough be in the first place secured, it is possible to commence on a portion of a well-designed plan, which may be afterwards enlarged from time to time. And if we compare such few details as those given us with those which we published last week with regard to the new Alexandra Dock at Liverpool, it would seem as if the engineer of the Tilbury Docks was resolved that the Mersey shall not continue to beat the Thames in the facilities which it offers for commerce. The *avant-port*, or tidal basin, in the Liverpool system, has an area of 7 acres; that at Tilbury is to have 14 acres of water-surface. The depth of the former is to be 44 ft. at high-water; that of the latter, 40 ft. at low-water. The entrance of the Liverpool basin is 400 ft. wide, as compared with one of 200 ft. in the Thames. This, however, is a matter for the hydrographer to determine. The most appropriate width is a question that depends on many conditions, on position with reference to the river, on direction of winds, tides, and currents, and the like. The Mersey is a far more difficult river to enter

safely than the Thames, and we see no reason to doubt that a proper width for the entrance of the *avant-port* has been adopted in each case.

From a tidal basin the entrance into a system of docks is practicable in more ways than one. The point which the engineer has to keep in view is how to obtain the greatest length of berthage or quay wall with a given floating area, due provision being made for the passage of any vessel to or from its berth at any time without interfering with any other vessel. This problem, when netly put, is not one of extraordinary difficulty. In the Liverpool case there is an approach to its solution by what we may call a gridiron arrangement,—that is to say, by the construction of branch docks at right angles to the main dock. This arrangement possesses the advantage of greater concentration. The length of quay wall and of accompanying railway will be much the same, however it is disposed. But to go from a vessel in one dock to one in another will generally be far more easy when docks are arranged in parallel lines than when one great line of quay extends for a long distance. That, however, is a matter of detail. There is land enough at Tilbury, water enough in the Thames at that spot, money enough, and engineering skill enough, at the disposal of the great dock company. We do not doubt that the new Thames port will be a credit to its promoters and a great benefit to the trade of London.

SOME ASPECTS OF THE TRADE UNIONS CONGRESS.

THE first Congress of the Trade Unions held in London took place, as every one now knows, last week, and has naturally excited a good deal of public interest, even on the part of those who have no special reason for following with interest the progress and ideas of those who are called the working classes. The contrast between the position now held by Trade Unionism in public importance and in public estimation, and the cloud of indignation under which the movement first struggled into existence, is certainly very remarkable. So far has the movement been able to mould public opinion, that one journal, in commenting upon its present aspect, observed that to revive old stories of trade-union outrages would now seem as unjust and inappropriate as to remind people of the barbarous practices of their ancestors. There certainly is a remarkable elevation of tone observable in the actions and utterances of the trades unions,—or, as we prefer to phrase it, "trade unions,"—within a remarkably short space of time; though, recalling one or two of the flagrant instances of narrowmindedness and injustice to employers which we had occasion to comment very strongly upon not so very long since, we are hardly prepared to see things quite so favourably in this respect as our contemporary seemed able to see them. Still, we fully believe that the idea of violent measures, such as amount to what the French call *voies de fait*, is quite discountenanced by all who take a leading part in the action of trade unions at the present moment.

The ugly facts which characterised the birth of trade unionism were, indeed, attributable to the same kind of causes as those which have often led to cruelties and violence being committed in connexion with the assertion of liberty. The working-men in the principal trades had long been at the mercy of the capitalists, and had been treated in a great number of cases with a most arbitrary indifference to the good of any one but the capitalist, under whose power they practically lay; for if one workman or shopful of men refused the terms of the capitalist, he could always count on getting others who would accept them, and to be the first to rebel was to commit suicide. The movement in the direction of combination as a means of organised resistance to this oppression by capital arose therefore out of bitter feelings of revolt against injustice and oppression, and exhibited naturally the violence which might be expected when a body of men, including among their numbers not a few ill-educated and morose spirits, found themselves in possession of a new and formidable weapon with which to repay their former masters in kind. While holding still the opinion that much of the early history of trade unionism, in some quarters of England more especially, was marked by proceedings that were perfectly disgraceful, and concerning which there ought to be no two opinions, we entirely concur in the feeling that this unhappy phase of the movement should now no more be recalled on the one hand than it should be justified on the other. Whatever faults or shortcomings the trade unionism of to-day may have, whatever mistakes it may make, it is thoroughly respectable and respected, and appears desirous not only to do what is right, but even to appear as the promulgator of social theories and aims in advance of the average social morality of the day.

In this latter respect, however, we must be allowed to suggest that the attitude and tone of the trade unions, as represented at this recent Congress, are a little too magnificent. Putting together a number of expressions and sentiments which were uttered by various speakers, it would really seem as if the trade unions considered themselves as the salt of the earth, and as the only body of people in the country who were actuated by the loftiest and purest political and social motives. This tone of what may be called corporate self-congratulation on all the good that "we" have done and intend to do runs through the whole of the proceedings, from the condemnation of the whole bench of magistrates, paid and unpaid, and the suggestions for their wholesale amelioration, down to the superb tone of injured virtue in which some delegates supposed to represent Protectionist or "Fair-trade" interests were alluded to as those who had come there to do "the dirty despicable work of those who were opposed to the interests of trade unions," and "to bring disgrace upon the trade unions of the country," apparently by holding and expressing opinions about trade different from those held by the Congress. The obnoxious delegates, or some of them, appear to have been technically in the wrong as to their standing-ground in the Congress; but, beyond this, we do not gather that they evinced any crime except that of being Protectionists; and though we believe the revival of the Protection idea to be in the main a mistake, the matter is not by any means so simple a one as the trade unions appear to think, and it might in any case have been useful, if such questions are to be discussed by trade unions, to listen to what those on the opposite side have to say. At any rate, the use of such overcharged expressions as we have quoted is very undignified; and as far as we can judge by the reports in the newspapers, it would seem that the obnoxious and finally ejected delegates had the advantage of the virtuous majority in point of temper and forbearance; but we admit that it is difficult to form a just impression on such points from mere newspaper reports. With regard to the unwise and sweeping charges against the magistracy of the country, we observe that one delegate had the courage and common sense to say that he entirely differed from the majority, and to point out, moreover, that, even granting the charges made were well founded, the resolution proposed suggested no remedy.

There is another criticism which is unavoidably suggested by the prevalent tone of the Congress, and which the leaders of the trade unions should consider seriously. It is impossible to blink the fact that they are recommending for themselves some of the very methods which they condemn in other classes of society, and that while they complain of and make war on the evils of class feeling and class legislation on the part of others, they are continually and strongly asserting their own class feeling. They boast, one speaker did at least, that they had a power in their hands which would enable them to] break down any monopoly and any class interest existing. They may or may not overrate their power in this respect; but, putting that aside, how are they seeking to establish and consolidate this formidable power of which they boast? Simply by endeavouring to establish a monopoly of their own, a monopoly of labour. We do not say there is anything immoral in doing so; we may go farther and say that their form of monopoly is of a more honest and healthy type than some of those against which they contend, certainly far more so than such a monopoly as that which the ring of cotton speculators in Liverpool have been seeking to establish for their own benefit, and which was referred to at the Trade Unions Congress in terms which were not at all too strong, and with which we quite concur. But it is really absurd for people to assume this high and mighty tone against monopolies of every kind and in favour of free trade, when they are actually working in opposition to free trade in labour. Are they entirely blind to the fact, which is certainly patent to most people of understanding, that by their own action in forcing up wages and forcing down hours of labour, and curtailing the private advantages to be derived from individual superiority of talent among themselves, they have to some extent checked the outlay of capital in building operations, and sent some branches of labour largely into foreign hands? Again, the trade unions are eloquent against class privileges, yet the assertion of the rights and privileges of their own class, as a class, runs through the whole proceedings of this Congress, and almost its very last business was the reading, with evident approval, of a letter from a "committee of invitation" in Zurich urging their co-operation at an International Working Men's Conference, among the objects of which was "to arouse class feeling." Now, class feeling is one of the very evils which, in regard to all the rest of the world, they profess to desire to break down, and one which we on our part consider to be a very great obstacle to general progress and general good understanding between man and man. The abolition of the idea that working men are a separate class is one of the very objects which the wisest friends of the "working class" have in view, and which we really supposed was an object with the most intelligent and best educated of the working men themselves. And even if it were otherwise, where is the logical definition of the "working class"? Where does it begin and end, and what are its boundaries? No one can say. Among the members of a single trade or profession there may be legitimately and logically a kind of class feeling, which is better and more pleasantly expressed as *esprit de corps*, and is in most senses a natural and healthy spirit. But there is no real line of demarcation between "working classes" and the rest of the world, except the line which certainly may be drawn between those who do some work and those who do none at all, but live only for indolent pleasure. Apart from these, all of us belong to the "working classes," and the work of handicraftsmen is not more important to the world than many other forms of work, and if the craftsmen are told that it is, by injudicious and one-sided friends, they will do wisely not to believe such a gospel. The workman of one day becomes a "master" the next, and any capable and instructed artisan should feel that he carries in his basket the brass plate of the employer. What is curious in connexion with the subject, as considered in regard to this particular Congress, is that by a singular unconscious irony, the working men were commended, in a leading article in the *Times* in reference to the Congress, for having shown the world that they did not consider themselves a class apart; while the daily reports of the proceedings of the Congress, in the columns of the same journal, went directly to show the contrary.

We make these remarks in an entirely friendly spirit, and in what we believe to be the best interests of the trade unions, who would do wisely to consider carefully the ground which they are taking, and to content themselves with a more cosmopolitan, and, in some respects, less ambitious programme. At the outset of the movement the peculiarly class attitude which they adopted may have been necessary to break down the opposite interests of the capitalists, the relations between the two being at that time abnormal and unfair. But the ultimate object should be, not to set up one class against another, but to obliterate the idea of class, and to recognise the fact that all workers have equal interest in the general good, and that class demarcations and class feeling are entirely conventional and injurious to the general welfare of the community, and to the best mutual understanding and mutual help. Nor are the trade unions entirely justified in the very large claims they make to be heard on subjects involving the widest political and social interests. There are no doubt many secondary subjects more or less directly connected with their trades, which they may most profitably handle; nor is there any very obvious reason why the trade unions should not discuss political questions and make recommendations upon such questions with the degree of weight their numbers and influence can give them. But this, again, is no reason why they should claim to adopt the tone, as they certainly have done, of paramount arbiters and advisers on such questions. Education is needed for useful discussion of such subjects. To read the way in which some of the speakers expressed themselves,—the working

classes would not "tolerate" this, that, and the other,—it might be supposed that they were, or had a right to be, the governing body of the policy of the nation at large. What would they say if a congress of representatives of professions, or representatives of the landed interest, used the same tone? What an outcry the trade unions would then raise against class arrogance and class self-assertion. The trade unions are entitled to their share in influencing public opinion, and to no more than their share, and the sooner they recognise this the better. We willingly and cordially say that their tone on public questions is in the main a high one, and that much that is valuable and suggestive on important questions may be gathered from the debates of the congress which has just closed, from among a good deal which was one-sided and sometimes intemperate; but the didactic tone which pervades their expression of opinion, sometimes on topics which really have no connexion with the professed objects of a trade-unions congress, is to be deprecated as both unwise and out of place, and not calculated to increase their influence with the more thoughtful of the outstanding portion of the community.

Some of the special points touched upon in connexion with the working of the building trades we should have been glad to consider more in detail, but must defer doing so, at any rate, for the present.

THE COMMERCIAL VALUE OF ART.

WE hear a great deal in the present day about art, and in some quarters there has even been the expression, generally misunderstood, of positive nausea at the constant discussion of the question. But while there exists this feeling, prompted, doubtless, by the large quantity of "irresponsible chatter," the echoes of which reach us through the press from every quarter of the kingdom, the importance of art in all its bearings, social, moral, and commercial, is never lost sight of by the more thoughtful; they are, indeed, every day reminded of this fact, which, of course, to a great extent, is the suggestive cause of so much that we hear now said and written concerning art.

Theoretically, the subject of art and its influence has been for a century and more discussed, and ably, often exquisitely, discoursed upon by the favourite authors of Europe and America, and it is on the basis of these theories that so much has already been done to test their practical value; for it has at length come to be generally conceded that art has other bearings than its connexion with the painter. The sculptor or architect is still, however, in many sections of our strange society, scarcely recognised as an artist,—a word carrying with it to many only the idea of connexion with the palette. Happily, among the more influential members of the community such views are rare, though unfortunate stories are current in professional circles regarding the treatment of eminent artists even by members of our Legislature.

The importance of art as an essential commercial factor in our wealth as a nation, is daily becoming better understood in our practically-minded community, so much so, indeed, that it is gratifying to find that we are admitted by rival nations to be seriously menacing them on their own ground by our products,—countries whose commercial renown has long depended on their superior reputation for artistic skill.

In the present day the custom is much in vogue of reducing matters to plain figures. Now art, though essentially entering among the theoretical amenities of our existence, is capable of having its value reduced to the crude logic of statistics, and to those matter-of-fact seekers into the details of trade returns, as also to those who may be somewhat sceptical as to the commercial value of art, we beg to submit some facts, relating, it is true, to a foreign country, but that country one which has long justly held a world-wide reputation for the artistic superiority of its products,—France.

In a recent number of the *Révue des Arts Décoratifs*,—the joint publication of the Paris Museum of Decorative Art and the excellent institution of the Union Centrale, to which reference has more than once in these pages been made,—appeared an admirable article drawing the attention of the French manufacturing world to the ever-increasing tide of artistic products imported from abroad. France has long borne undisputed in the commercial world the palm in this respect, but within a few years foreign nations, aided by excellent systems of art-education, have succeeded in commencing a formidable rivalry to France and French products. France, satisfied with the reputation it has borne, has neglected to keep pace with the movement, and the more thoughtful members of the community foresee the possibility of a near future in which France may be beaten out of the markets of the world, and on the very point for which her products once held the foremost place. Such is the cry of alarm the writer of the article to which we refer has thrown out. His view he supports by figures.

In the first rank of art in the ordinary acceptation of the word, application is made to the statistics of the annual exhibitions. It would appear that of the exhibitors in this year's *Salon*, 1,439 were French, and no fewer than 416 were foreigners. On such facts, of course, no great stress can be laid. France in such a field can well afford, and in no way grudge, to spread abroad pupils who possess the mastery of their art which it would seem French institutions so successfully teach.

In a more practical direction the menace of foreign competition is evident. Comparing the statistics of 1880 with those of 1859, some definite results may be obtained. In 1859, France imported 61,650,000 francs worth (say two and a half millions sterling) of objects made abroad, a figure totally exclusive of all raw material or food-stuffs. In this total, half a million sterling was for objects acquiring value by their artistic worth. In 1880 the importations were 448,347,000 of francs (some eighteen millions sterling), a total in which enter some six millions of artistic products, the difference of four millions in the twenty years showing clearly the extent of foreign competition.*

Against the statistics of imports, let us now place those of the exports in the same year. Here, taking certain items (decorated cotton tissues, works in copper gilt, porcelain, playing cards, and cut coral) there will be found in the two columns ranged side by side a great diminution for the year 1880 as against 1859, but ample compensation is to be found in the characteristic items of millinery, books and engravings, bronzes, *objets de collection*, fashions, flowers, furniture, and jewelry,† almost each item of which, as reference to the details in the note will show, represents millions sterling. In all these instances it is to art and its application that is due the chief value of the products. It will be seen, we hope, that the commercial importance of a proper consideration of art and its practical application is worthy the attention of those unsympathetic with the more theoretical and æsthetic interests believed to be associated with art and artists. Such views are now, happily for the world at large, steadily gaining ground, with the direct result of causing France to look inquiringly into the boasted supremacy on which she has so far trusted and still continues too confidently to trust.

Statistics show that the exports of French products owing their commercial value to their artistic qualities amounted in 1859 to 665 millions of francs (some 26 millions sterling) and only 766 millions (30 millions sterling) in 1880, in twenty years an increase of only 15 per cent. In the former of these years one million sterling worth of artistic products was imported into France from abroad, and in 1880 no less than six millions, an increase of 488 per cent. We do not wonder that, in the face of such figures, there appears to the thoughtful Frenchman necessity for a cry of alarm at the danger signal ahead.

On our side a moral can also be drawn. England stands foremost among the rivals of France; within a generation England has made rapid strides in the direction of its art manufactures, as they are understood, and we owe this advance in great measure, not alone to our increased attention to art education, but to the wise foresight of many large employers of labour. Much, however, remains yet to be done: many efforts have to be made and results achieved in this direction. The commercial supremacy which France has so long owed to its artistic superiority,—a superiority it held almost undisputed as long as other nations remained in this respect behind-hand,—England may take, if not in totality, in great part at least. To the reputation we bear for the solidity and honesty of our products,—those chiefest elements of all truly artistic work,*—let us but add the grace, the elegance, and the due consideration to adaptability to use, qualities which are more generally understood to constitute art, and we may, as we already do in a great measure, hold a high position in the world for the artistic excellence of our products. It remains in the hands of our manufacturers, of our great employers of labour, of their numerous workmen and their directors, of the younger generation who are growing up under the teachings of daily-improving and increasingly-wealthy and endowed institutions. With the extension of the system of technical training, with the innumerable means now afforded of increasing, not alone our power, but our happiness, by the acquisition of knowledge, by the funds of originality suggested by a proper study of the contents of the storehouses of the art and industry of the past, our museums, we have it at our disposition to make an effort in a direction the attainment of success in which has at all periods of history formed the noblest aim of nations. To do this, and, in doing it, to raise our existence from the clinging horrors of sordid pursuits, to shed on the lives of those about us, in due proportion, the blessings of cultivation and refinement, would justify a large expenditure: it would be worth no small sacrifice to obtain in the commercial markets of the world as envied a place for the artistic value of our products as they long have held for their sterling worth and well-trusted honesty.

* Furniture in 1859, 1 million of francs; in 1880, 4½ millions; *objets de collection*, 2 millions against 10½ millions; arms 1 million against 2½ millions; cut coral, a quarter of a million against 2½ millions; wall-papers, 598 francs (!) against 1½ million; porcelain and faience a quarter of a million against 4½ millions; glass, enamel, &c., 1½ million against nearly 3 millions; books, 2½ millions against 4½ millions; jewelry, a quarter of a million against 5½ millions; engravings and lithographs, less than half a million against nearly 7 millions.

† Exports: jewelry, in 1859, 15 millions against, in 1880 52 millions of francs (a million of francs is 40,000*l.*); fine mercery, 58½ millions against 85 millions; fashions, flowers, &c., 10½ millions against 32½ millions; furniture, 7½ against 15 millions; *objets de collection*, 2 millions against 14 millions; books, engravings, 18 against 28 millions; wall-papers, 5 against 6½ millions; bronzes, 5½ against 9 millions; sculptured marble, half a million against 1½ million; sculptured stone, half a million against 730,000 francs; false stones, &c., 8 millions against 11 millions.

THE MEMORIAL WINDOW TO MARY TUDOR.

IT has been announced that the Queen has just presented to the Church of St. Mary at Bury St. Edmunds a stained-glass window, in memory of Mary Tudor, the daughter of Henry VII., known in English history as "Mary the French Queen," from her marriage with Louis XII., but to our neighbours more familiar as "La Reine Blanche," the incidents of whose life suggest the decorative motive of the window.

The story of Mary Tudor forms one of the many links that exist between the history of our own country and that of France. The young "Marie d'Angleterre," if scarcely as familiar to the French as is with us the French queen of Charles I., Henrietta Maria, has left in France a remembrance more than is attached to one merely of the many figures in the history of the country. Among the most widely spread of these associations is perhaps the connexion of Henry VII.'s daughter with the Mediæval building in Paris, now known to the public as the Musée de Cluny. Every visitor to Paris will remember the peculiar character of the Cluny Museum lodged in the quaint hôtel in which M. du Sommerard (the father of the present excellent director) had gathered the collection which was purchased from him by the French Government in 1843. The rooms of the former dwelling-house, now the museum, have to a great extent been left in their original condition, or, like the architecture of the rest of the building, have been restored. Of these rooms, that next the chapel,—the beauty of the architectural remains of which is familiar to every professional student,—bears the name of the Chambre de la Reine Blanche, a memory of the stay made at the Hôtel Cluny, in January, 1515, by the young widow of Louis XII., Mary Tudor, during the days of her mourning. An air of romance seems to linger round the room, which,

* When the Carlyles, as we see by the recently-published "Reminiscences of Carlyle," were about to leave Scotland for London, Mrs. Carlyle wisely determined to bring with her the family furniture, on the score of its solidity and honest workmanship. "Respect what is truly made to its purpose, detest what is fal-lal, and have no e-uvers with it." "My own heart," remarks Carlyle to bi-se f, "could not have been more emphatic on that subject . . . . My writing-table, solid mahogany, well-devised, always handy, yet steady as the rocks, is the best I ever saw. No book could be too good for being written here, it has often mutely told me."—See "Reminiscences of Carlyle," vol. ii., p. 189.

we cannot doubt, affects even many of the English and American visitors who pass through the museum without a thought of its historic memories, and still less its connexion with "home." The Chambre de la Reine Blanche is familiar to every artist who knows Paris, and often has served as a suggestive background for some *Salon* "hit," for the room retains much of its old decoration, which, when the hôtel was put in order, was discovered under the more modern paperhangings. The paintings, characteristic Renaissance works of the reign of Henri Deux, and representing groups of Italian ruins, with accompanying garlands and medallions, were in a sufficiently good condition to bear restoration, and they still exist to show to the present generation an excellent specimen of the domestic decorative art of a period which is now much in favour.

The residence of the young English queen at the Hôtel Cluny appears on historical evidence to have been at the invitation of Francis I., who had succeeded his father Louis XII. "The king gave order, we learn from the secretary of Cardinal Duprat, that the Queen Marie, widow of the late King Louis, should be honourably entertained, and the queen came to lodge at the Hostel de Cluny; the king coming often to visit her, and paying her every attention in his power." The chamber occupied by the princess has retained to this day, as we have already remarked, the name of the Reine Blanche, it having been the custom for the French queens to wear white during their days of mourning. Mary Tudor's mourning was not of long duration; she, indeed, regretted but little the royal husband who had been forced upon her, and who, on his sick bed, had, as he told her with much courtliness, given her as his New Year's gift her freedom by his death, and but a few weeks passed before the young widow, who had been warmly aided in the affair by Francis I., married an old flame, the handsome Charles Brandon, Duke of Suffolk, the original of one of the extraordinary series of portraits we owe to the patient exactitude of Holbein, and which was exhibited, it will be remembered, some years since at South Kensington. At the same exhibition there were two portraits of the duke and his wife, one by Holbein, the other by Mabuse, both bearing the famous and familiar lines:—

> "Cloath of Gold, doe not despise,
> Tho' thou art matcht to Cloath of Frize;
> Cloath of Frize, be not too bold,
> Tho' thou art matcht to Cloath of Gold."

As a fact which still further shows the many links existing between our own country and France, the daughter of Henry VII. had been married to the French king in the then royal palace of the Tournelles, the home since the Middle Ages of the French court, and occupied during the fifteen years' possession of Paris by our English troops at the commencement of the fifteenth century, by the Duke of Bedford, the regent in France of Henry V. of Agincourt fame, the father of the young Henry VI. who was so pomposly crowned King of France in the Cathedral of Notre Dame. The home of the Regent Bedford disappeared when the court moved to the Louvre, built by palace-loving Italian-bred Catherine de Medici, and on the site of the Mediœval palace of the Tournelles, with its pepper-castor shaped towers, now stands the seventeenth-century red brick Place Royale, better known to Republican France as the Place des Vosges.

A word more on an incident connecting additionally the past of the Cluny Museum with the history of England. Not many years after Mary Tudor had left behind her the tradition of her residence in the old hôtel, was celebrated within its walls the marriage of James V. of Scotland with Madeleine, the daughter of Francis I. It was from this union that was to spring the unfortunate queen, whose sad story is one of the most familiar of the romances of history,—Mary Queen of Scots.

Highbury Vale, London. — St. John's Church, which has been erected from the designs of Mr. Wm. Bassett-Smith, has been consecrated by the Bishop of London. It has a spacious and lofty nave, five bays in length, with north and south aisles; a chancel the same width as the nave, with a five-sided apse and aisles on each side. It provides accommodation for 820 adults, and the cost of the building has been about 7,000*l.* The works have been carried out by Mr. M. Manley, of St. George's-road, Regent's Park, under the direction of the architect.

THE DUST-HOLE.

NOTWITHSTANDING the modern love of luxury,—and especially the luxury that consists in a high degree of comfort and cleanliness,—we are not quite aware whether modern ingenuity has devised a perfect means of successfully housing, until its removal, the accumulation that we erroneously call "dust," but which actually consists mostly of decomposing and decomposed matter, with the peculiar nature of which most householders are familiar. The care, the labour, and sometimes, for their own sakes, the thrift of our domestics, contrive often to keep the offensive dust-hole at a sufficient distance from the eyes and nose of the owners of large houses to make a few of us, perhaps, unacquainted with the horror of this portion of the lower regions of our dwelling-places, but there are few of that numerous class in whose careers we are all so much interested,—the servant-class, as they are called,—who have not to endure every day of their lives the inconvenience and the actual danger arising from the dust-hole.

Here and there we find the situation of the dust-hole in the lower regions, ingeniously contrived so as not to be altogether unsightly, but it has an unfortunate way of asserting its presence; under any circumstances it occupies a space of ground, and pays ground-rent sufficiently important to call for some thought as to whether its room is not of more value than its company. But how, it will be asked, is the dust-hole in our houses to be got rid of? The contents of the dust-hole were once considered of value. Contractors were glad to take upon themselves the task of removing the dust from our houses; but things seem to have changed in this respect, and the business appears too large for the ordinary mind to grapple with, and complaints are now constantly made of the parish authorities whose duty it is to clear out the contents of our dust-holes whenever the accumulation requires. Some steps, it is evident, therefore must be taken in this direction.

Why should we not have recourse to the Parisian principle of doing away altogether with the dust-hole in our houses, and adopt the plan so successfully pursued by our neighbours of removing the accumulation of twenty-four hours, placing at the door of each house a movable receptacle containing the dust, and the contents of which are taken away before a certain hour in the morning by properly and strictly controlled contractors? In Paris the contractors are the municipal authorities, who, with the assistance of the police,—who have a certain control in the matter,—secure for the smallest apartment or the largest house a freedom from that horrible offensiveness that a dust-hole possesses after a few days' neglect, and from which, indeed, it is never entirely free from the imperfect manner in which, from its shape and the nature of its contents, it is emptied. The dustman and the *chiffonnier*, or rag and paper gatherer, in Paris, are the industrious removers and utilisers of the refuse of the town; they serve, indeed, as the human insects, the scavengers of nature whose use Sir John Lubbock could doubtless tell us so much about, and without whose action the world would be seriously inconvenienced.

The dust-question is one which would seem to puzzle not a few communities in the present day. Our practical cousins in New York have long allowed themselves to suffer serious inconvenience from the management of their dust-barrels which so unpicturesquely litter the "side-walk" of their streets, every puff of wind scattering in the air the varied contents of these neglected and unremoved dust-bins. But American ingenuity, although unable apparently to combat the glaring mismanagement (to say the least of it) of the municipal funds supposed to be devoted to the cleansing of the streets, has, we learn, devised a method which promises, to some extent, to reduce the evil of the storing of the decomposing matter,—which forms, in reality, the chief difficulty of the unemptied dust-hole.

A paragraph in the current issue of *Scribner's Monthly*,—a magazine whose practical treatment of social questions is by no means allowed to decline in favour of its exceptional artistic qualities,—describes a small and inexpensive crematory stove for the consumption of household rubbish. It has long been a custom, and a very objectionable custom, known to the cook and housewife, to throw on the fire much of the kitchen refuse, with the result, arising from the imperfect combustion of a mass of damp material, of producing an intolerable stench. The new American crematory stove is described as consisting of a zinc pail fitting on to the hole in the top of the ordinary kitchen stove or range, and by a simple system of double interior forming into a desiccating machine. The rubbish, when fully dried, passes into the fire from the pail by a false and movable bottom, and is, of course, rapidly consumed. As a means at the disposition of every householder of utilising his refuse, the new crematory stove promises something; it is, however, but a half remedy for the unsightly, unsanitary, and needless infliction of the regulation dust-hole, whose contents in a well-organised community should without fail be removed every day.

THE "LIVADIA" AT HER LAST MOORINGS.

WE confess that we entertain a horrible suspicion of a certain class of asserted scientific discoveries. We refer to such as drive, like a thunderstorm, in the teeth of the fair winds of either ancient learning or of modern progress. Not but that there are ebbs and flows in the great tide of science, or that that which was but yesterday thought to be a gain may by the experience of to-day be shown to be a loss. Of that we have abundant example. But we rather refer to what we take to be a special characteristic of the present day,—the discovery *ab ignorantiâ*. It consists in neglecting two or three of the essential elements of a compound question, and then finding it very easy of solution. It is as if, in an equation in which x and y are both unknown quantities, you assume that x *must* equal ten, and then proceed to solve the equation. It is like the reform in painting which consists in omitting aërial perspective, and paying scant heed to accuracy of drawing. It is like that pseudo-science which affects to predict the course of human affairs, leaving out of view the peculiarities of human nature. It is the improved version of "Hamlet," with the part of *Hamlet* omitted.

Such seemed to us to be the character of the blast of trumpets, penny and other, which welcomed the launch of the *Livadia*. Great names stood as godfathers to the vessel. An Imperial Admiral had adopted the ugly babe. Special correspondents baptised its first trip with champagne; and a gentleman considered to be a high authority on the construction of ships threw all the weight of that authority into the scale of praise.

We were members of but a small minority. We are not aware whether any other members of the Press ventured to hint a doubt, or hesitate dislike. From the first we were of opinion that to revert to the primitive form of the tub, even more ancient for flotation purposes than the square coracle of the ancient Britons, still to be seen on the Towy, and not unknown to boating men at Oxford, could be nothing but a blunder. We waited for details of the first voyage of the *Livadia*. It was not made at the speed promised, but such excellent reasons were given, as to prudence in steaming slow, for fear of meeting a fog, or something to that effect, that we thought the apologies more suspicious than the delay. Then some floating wreck knocked a hole in her bottom. One or two trifling accidents kept the vessel from proceeding on her cruise. She was a great success,—every one knew that. Great authorities proved that; and the present of 40,000*l.* to the builders completed the overwhelming proofs. Still, in spite of all, the *Livadia* lingered at Ferrol, and the demonstration of the great success was postponed to a more convenient season.

A more convenient season, at least for the opponents of the *Livadia*, has now arrived. A commission has sat in judgment on the famous yacht, has tried the *Livadia*, and found her wanting. "She is slow, she rolls heavily, she is too weak, and she is made of bad materials!" We cannot but suspect that here the pendulum has swung too far in the opposite direction. That such a cross section was utterly inconsistent with speed or with economy of steam power, we stated in the first instance. No one familiar with the result of Mr. Froude's beautiful experiments on the forms proper for ships can doubt that. Whether she rolls heavily we cannot say. The very aim and object of her being was,—not to roll; the fair-weather description of her one voyage dilated on her steadiness. Here, then, we should like some more reliable evidence than that of the Imperial Commission, which has

discovered that the unfortunate ship is built of bad materials. As to that, we shall probably have a word or two from the builders, who received so substantial an acknowledgment of the excellence of their work. That the vessel was not strong enough is a natural vice of her design; and we are inclined to suspect that the three distinct propellers may have so acted as actually to tend to tear the vessel asunder. We think that the report of the Commission bears more sign of political bias than of engineering investigation. But as to the condemnation, and the necessary condemnation, of the *Livadia*, there is no doubt, although the Commission have done their best to render ridiculous their own report by recommending that a smaller *Livadia*, on the lines of the turtle ship, should be constructed out of the materials of the demolished monster, not of the deep, but of the shores.

BUILDING AND ENGINEERING CONGRESS IN DANTZIC.

The tenth assembly of delegates from the associations of architects and engineers in different parts of the German Empire, has recently been held at Dantzic under the direction of the Central Union of these societies. The proceedings are interesting to English members of the two professions represented, as in addition to dealing with the official and technical subjects which naturally were discussed, the delegates gave much attention to matters affecting the relations between their societies and the respective Governments to which they are subject, as well as to economical and other topics which refer to the connexions of professional men with the community at large.

The total number of societies represented at the Congress was seventeen, and the number of delegates thirty-two; the total votes were fifty-six. Of the twenty-six societies which compose the Union, nine were absent, but the composition of the assembly was such as to make it represent with fitness the two professions as they now stand. The societies belonging to certain provinces or districts were those of Bavaria, Saxony, Middle Rhine, Lower Rhine and Westphalia, Schleswig-Holstein, West Prussia, East Prussia, Brunswick, and Thuringia; while the societies attached to particular cities were those of Berlin, Hanover, Hamburg, Breslau, Dresden, Lübeck, Bremen, and Aix-la-Chapelle. The central authority was represented by Herr Professor Köhler and Herr Schwering, the former being president of the assembly; the vice-president and secretaries being selected from amongst the delegates.

The proceedings commenced on Monday, the 29th ult., but the bulk of the delegates and visitors had arrived by the preceding day, and had had an opportunity of meeting in a social manner, so that old friendships could be renewed and new acquaintances formed before the official inauguration of the Congress, which took place with due formality on the morning of the 29th, in the Council Building of the Municipality. The financial statement showed an expenditure of about 100*l.* by the Union during 1880, leaving a balance of about 70*l.* in hand. During the Congress resolutions expressing the thanks of the delegates for the reception accorded them by the civic authorities were cordially approved, and its duration was marked by several gatherings of a social character, which were fully appreciated as agreeable variations from the technical and economical discussions of which the proceedings of the Congress in a great measure consisted.

Proceeding now to record a few of the leading subjects of discussion, we note that the important subject of uniformity in technical nomenclature has met with a full share of attention. It is proposed to continue the special committee charged with the question of the uniform designation of mathematical and technical dimensions, the labours of which are progressing satisfactorily. The suggestion made at last year's meeting by the Leipsic society as to the nomenclature of the different floors of buildings, has been since then approved by many of the other societies. In this system, the floor wholly or partly underground, is called the cellar-story, the next the ground-floor, and the higher ones, first, second, and third stories. Intermediate stories of a subordinate character are called half-stories or mezzanine floors. It is stated that in Prussia certain official regulations stand in the way of the general introduction of this system.

The results of experiments as to concrete building, it was stated, will be published very shortly in one of the German technical papers, and therefore the question was not discussed.

The value of accurate details of a technical nature as to buildings and engineering works has long been recognised by the Central Union, and eight societies have collected in tabular form a variety of information as to 736 architectural and other works. An obstacle has been placed to the completion of this valuable work in its original extensive form, by the refusal of the Prussian authorities to furnish details of the State buildings under their charge. The Government has been for some time preparing for publication details of the same character as to all Government works executed since 1870, and therefore the authorities decline to help the Union in the matter. The information collected is, however, of such a valuable character that the Congress resolved to entrust the executive committee with the task of utilising the materials in their hands in the most suitable manner, either by publishing them separately, or by joining with the Government, in order that the work on which the State is engaged should be as complete as possible, and should serve as a standard book of reference for the building and engineering professions.

At last year's Wiesbaden meeting the invitation of the central body for members of the profession to exhibit plans of dwelling-houses had been amply responded to, but the collection was not typical of the domestic architecture of all parts of Germany. The assembly then approved a proposal made to publish the plans sent in, and to obtain such additional elements as would give the work a thoroughly representative character. The labours of the Mid-Rhenish Society in this direction have been successful, and the publication of this work seems assured, although more exact details cannot at present be announced.

Another work, prepared under the auspices of the Union, and which is nearer publication than those to which we have alluded, is the illustrated volume on wood-architecture now being brought out by the publishing firm of Ernst Wasmuth, of Berlin. Some proofs of the earlier parts of the volume were submitted to the meeting, and after a discussion of some length as to whether the illustrations should be photographic delineations or merely ground-plans and elevations, the meeting resolved to forward in every possible way the production of this useful work, and contributions were invited from those societies whose districts were not represented in the information now before the compilers of the book. It is expected that the volume will appear at latest within a year, and the fact that the publishers are undertaking all risks in connexion with it would seem to indicate their high appreciation of its technical merits.

Other matters of a professional nature were discussed which had been the subject of debate at previous meetings. In addition to these many new topics were introduced on which further information is looked for by the time of the next assembly. Amongst these we may notice the subject of the situation of young architects, and the question whether there is any means of improving the general position of the junior members of the profession in Germany. The improvement of the instruction at the practical schools was also touched upon, with a view to more complete discussion on a future occasion. Amongst the strictly technical points which were dealt with in a similar way, we notice questions as to the preparation of stones for building, and the use of glazed tiles for roofing purposes. These matters will be again treated at next year's meeting, when the experience of the various societies will be brought to bear on their discussion and ultimate elucidation, for the benefit of the building interest in general.

The questions of a more public character which occupied the attention of the Congress are such as to claim particular notice, as they deal with points affecting the relations of the professions with the different Governments and with private individuals.

The codification of the German civil law has been kept in view by the Union, and will still remain before it, although there is no immediate occasion for action. The publication of the work dealing with legal precedents affecting the responsibilities of architects and engineers towards the persons employing their services, is to be proceeded with on the basis of the materials which are collected by the end of this year, and the work is expected to appear in April, 1882. It has for some time engaged the attention of the Hamburg Society, and will include models of contracts and other information of value as to legal matters.

A most important subject of discussion, affecting the external relations of the Union, was the question of statistics as to building matters, which has for ten years been receiving the attention of the central body. The Bavarian society first suggested the collection of statistical information in such tabular form as would be valuable for purposes of reference to those interested in national economy, hygiene, and other sciences of a practical nature, while serving as a text-book for architectural students. The result of its experience has, however, led the Union to the conclusion that, as a central body, it is not in a position to bring the work to a successful termination, and that the intervention of the State can alone accomplish that end. It was, therefore, resolved that the Berlin Society (in conjunction with those of Bavaria and Hamburg) should prepare a memorial setting forth, with all possible lucidity and conciseness, the different points which require the attention of any public body undertaking the work. This memorial will be presented to the respective Governments interested, and, as it will summarise the work already done, it will, no doubt, facilitate the acceptance by the different authorities of the responsibilities which the Union invites them to undertake; in the carrying out of which, however, it promises to assist in every possible way.

An equally important subject of discussion was the altered position of the Union towards the International Patent Congress, in consequence of the absence of Germany from active participation in that assembly, and by the adoption of certain projects opposed to the wishes and interests of the German nation. The committee which had been engaged in watching the interests of Germany, being thus deprived of the means of action, did not, however, consider its mission ended, but set about the formation of a new organisation for the protection of German patent interests. The question before the Congress was whether the Union should as a body support this proposal, and although the presiding committee was in favour of the continued participation of Germany in this international question (with a view of preventing the country occupying possibly an isolated position), the decision of the assembly was for an opposite course, and such will therefore be adopted by the Union.

Amongst the subjects on which discussions were commenced (with a view to their more thorough ventilation next year) was the important question of the diffusion through the press of information as to building and engineering matters. One speaker attributed the general absence of such topics from the newspapers of the day to the apathy shown in many technical circles as to this subject. A resolution was adopted inviting the co-operation of the different societies forming the Union, in the work of diffusing through the daily press accurate information as to the transactions of the Congress, and thus enabling the general public to follow the development of building and engineering science. The technical press also received its share of attention during the Congress. The details published during the year as to technical societies in other countries by the Union were briefly considered.

The programme of the Congress included visits to some of the most interesting architectural and engineering works in the neighbourhood. Under the former head may be classed the Rathhaus (built in 1350), the Marienkirche (built in the fifteenth century), and the Franciscan cloister, which dates from the same period.

The water supply and drainage systems of Dantzic attracted the special attention of many professional visitors. Within the last twelve years these have witnessed the execution of improvements which tend to place Dantzic in a favourable sanitary position.

The harbour was also an object of interest, and an agreeable diversion from the fatigues of theoretical discussions was afforded by a trip in a steamer to the neighbouring harbour of Zoppot.

While thus giving a general idea of the scope of the Congress, we have had to pass over in silence many matters which might have proved interesting. Those mentioned by us will, however,

give some idea of the present position of technical matters in Germany, and if we take into account the attention which has been called to the practical parts of the sciences of building and engineering by this year's exhibitions at Brunswick, Frankfürt, and other places, it cannot be considered that a more fitting climax could be arrived at than that afforded by the theoretical congress at Dantzic, a report of whose deliberations we have endeavoured to present (though necessarily in an imperfect shape) to our readers.

KEIGHLEY AND ITS TRADE.

THE towns in the West Riding of Yorkshire are usually more distinguished for industry than for architectural beauty or for their historical associations; but one of the most notable,—Keighley,—is of great interest from its antiquarian associations, has had of recent years a marked and rapid growth, and has become a centre of one of our great trades. In the deep valley, at the junction of the little rivers Worth and Laycock,—if they may be called more than rivulets,—is the town which gave name to, and long sheltered, a knightly family, from which the dukes of Devonshire trace their descent. In the stormy days of civil war, Keighley was occupied by the Parliamentarians, and in 1645 there was a sharp attack and recovery. If, however, we leave the era of battles and bloodshed, and come down to the present century, we may find, in the comparison of the town as it is and as it was, one of the indications of growth of industries and of towns, of which Yorkshire affords many examples.

The irregularly-built little town had about half a century ago its full supply of water, and its gas supply; it had a neat court-house; the Leeds and Lancaster Canal gave it ample facilities for water conveyance; but the era of the railway was not. Its ancient church had been rebuilt at the beginning of the century; and that handsome structure, with its fine steeple and its "exquisite" clock, was one of the few ornaments of the town. There were seven or eight Dissenting chapels, and a free grammar school; and a mechanics' institute was in course of formation. About the town was an oasis of beauty,—blue heath on rugged hills contrasting with the fertile valleys, whilst the Aire was not then so much the reservoir of mills as it now is. The trade of the town in those days was largely in stuffs, worsted yarns, and cotton; the population, which had been 5,745 for the parish in 1801, had risen by 1831 to 11,176; and there were all the indications of further growth. There were in the town three cotton-spinning firms; there were curriers and leather-dressers; one or two hat manufacturers; three reed and heald-makers; and the like number of spindle, roller, and flyer-makers; whilst of worsted spinners and stuff manufacturers there were some thirty or so, but many of them were on a small scale. To Bradford, Leeds, Preston, Skipton, and Halifax, coaches went daily; there was the conveyance by water that has been hinted at; and there were half a dozen carriers. Finally, the state of the trade of the town is indicated by the fact that there was one postal arrival and despatch daily.

"Railways," said Carlyle, "have set all the towns of Britain a-dancing," and they have had their effect on Keighley since the opening of the Worth Valley Railway. The two great cotton-mills of Sir Richard Arkwright still lift up their tall heads; and worsted and cotton spinning, but in its wider form, constitute the chief trade of the town still, though there has of late been the introduction of the machine trade in one of its branches on a scale of some magnitude. Not so much a rapid as a steady growth has been known by the trade of the town, because the tendency has been in the textile trades generally to keep in the villages and to increase them as a whole, and hence it is that the growth of the West Riding, apart from the very hilly part, has been so general. But at the present time the tendency is becoming a little more marked to concentration in different localities, and it is to this that we have to trace the growth of the population of Keighley from 11,000 half a century ago to over 24,000 in 1871, with that growth since which the recent census has just shown. Except in the way of addition or extension, and in the smoothing down of some of the parts that showed its irregular character, the chief feature of Keighley has been its filling up and its attainment of some of the characteristics of towns. Its church and chapel accommodation has been increased, and it is possible that, though it cannot compete with its great neighbours yet, Keighley may show in time an order and an arrangement that will be creditable to it in its once-straggling buildings. It has for over fifty years been one of the centres of mechanics' union effort, and the work done by its institute is far above that accomplished in some towns of greater pretensions. In a recent year, that institute reported that the total number taught by its classes exceeded 900; that in that year, as the result of steady honest hard work in competition with other youth, a Keighley lad, taught at the trade-school, had gained scholarships of 210*l*. That trade-school is one of the features of Keighley, and this is due, in a very large degree, to the patronage that the Duke of Devonshire has accorded it; whilst various scholarships, maintenance grants, &c., sustain the connexion between it and the elementary schools of the town. About 140 usually attend the trade-school, and the work done, especially in the machine construction and practical chemistry classes, has long been noted as excellent. In the schools of art attached to the institute some scores of students yearly derive benefit; whilst in other branches of study the institute of Keighley is in a very considerable degree performing the work that its early promoters had in view. Its membership is usually from 2,100 to 2,400, or more than a twelfth part of the population; its annual income is from 1,500*l*. to 1,700*l*.; its library is of 6,000 volumes; in the penny bank there is yearly deposited about 1,300*l*.; and there are other indications of its value to the town, and of the after-results that must be expected to flow from the inculcation of the principles it teaches.

In this district there is that sturdy dogged type of character that Miss Brontë loved to picture in her little home three miles away. From the busy streets of the noisy town of Keighley, brawling ever and anon at its guardians' meetings, the mind turns to that pretty walk up the Worth valley to Haworth, where "Jane Eyre's" writer lived and loved her stern but beautiful moorland, and the people who dwelt there who merited the description "frosty but kindly." This is the phrase that may be said best to depict the town of Keighley, for a hard, shrewd, money-making race dwell therein, and the trade of the town is safe in their keeping. The want of minerals gives not that promise of rapid growth that the north-east of Durham and Yorkshire shows, but there is a steadiness in the trade, and a solidity in its growth, from decade to decade, that is not always associated with rapidity. And with a continued increase of that town feeling which produces public-spirited citizens, and provides for the people all the essentials of town life, there should be a still greater and higher future for the town, and a still more rapid increase of its trade. It has capital, enterprise, and technical skill; it is likely to enlarge its trade facilities; and it is giving to the growing generation that practical knowledge which will lead to the better use of the former advantages, so that the future success of the town and trade of Keighley should be assured.

ENGLISH AND ITALIAN ART WORKMEN.

It is interesting to contemplate the difference between the art of the past and that of the present, and the difference between the modes of art production in past days and the art action of those who brought it into being, and of those who now bring art into existence. We know well enough, for it is sufficiently familiar, how a work of art, speaking generally, of to-day, is more or less rapidly, though by degrees, brought into being, and how many there are at times engaged in its production, *e.g.*, a painted glass window, or a group of statuary, not to speak of the decoration of a building. But there is a question of modern art action which, at the present moment, would seem to be of more than usual and passing interest, and it is that of the desirability of employing foreign art help; in other words, Is it possible, and if possible, desirable, to employ foreign workmen, with a distinct and individualised art and fine art of their own, to assist and even to lead in the production of an art, or architecture, with its ever-present sculpture and other decoration, foreign as art to such workmen, be the status of such workmen what it may? A recent letter bearing on this subject, by a student and workman who has sought out work in classic Italy and failed to obtain it, is suggestive, and points to matters artistic not a little curious.

In the first place, there is not, and can hardly be, an art-subject more curious and suggestive than that of the entire isolation of the nationalities and the fine arts of them of the distant past. If we go to antique Athens and try, as best we may, to realise the aspect of that famous city, so full of art, every street of it a museum, nothing probably would be found to be more striking than the isolation, and the sameness, so to put it, of its art, all about, and everywhere, and in all objects,—from its public buildings, its temples, and its monuments, down to the very commonest and most familiar articles of domestic use, its houses, and the furniture in them. All is Greek, and Greek only, and all is done by Greek hands, and the "handwriting" of such workmen is Greek, and Greek is as visibly written on it, and is as evident to the eye and mind, as is the nature of the material out of which it is wrought. There is no sign of foreign workmanship anywhere, or evidence of the existence of bodies of workers drawn from a distant and strange nationality. All and everything is Greek, and Greek alone. Free trade in art certainly did not exist in antique Athens, and the very isolation of the place, and its working for and exclusively by itself, whatever the disadvantages of such a course of action otherwise might be, had, there can be no doubt, this one advantage,—that it fostered a distinct and isolated nationality and language, and with them, a distinct and isolated art character of architecture and sculpture.

It was the same with Egypt and Assyria, for what can there be more isolated and fuller of individuality than the art and the architecture of old Egypt? To have borrowed anything, no matter where from, would have been to the Egyptian an all but impossible act,—he could not have done it. To have added anything foreign, any strange form or element, to his own special work, would have destroyed his art-faculty and instinct, and would have extinguished his very nationality. Indeed, may we not go yet further, and affirm that his architecture, great as it was, and as it yet is in its ruins, growing up, as it seems to have done, out of the necessary plans of his huge temples and temple arrangements and ritual requirements, could not have been at all, had he borrowed anything, or had he left his Nile river-banks for a foreign idea or for a foreign workman? And may not the same be said of the Assyrian, on another continent, for he was alike isolated, and with an art instinct and idea of his own, and certainly with an *architecture* peculiar to himself, so well fitted for the purposes and special uses to which he put it? The Assyrian, be it borne in mind, was on a level, as near as might be, with the Egyptian, and in the same stage of "civilisation," to use that somewhat ambiguous phrase, and, with the Egyptian, made up no small part of the world of that now so-far-off day.

We have thus but just glanced at the past of art, and at its mode of production, for the purpose of calling a moment's attention to the difference between it, and our modern and of to-day modes of doing the same work, and in the main, and speaking generally, for the like purposes; for, after all, human nature is the same all the world over, and through all recorded time. In the past, then, we see a number of distinct and isolated centres of art action and power; but in the present how different is everything! All is simply reversed. Art isolation, in the antique sense, has all but vanished, and art is day by day growing less and less distinctive, and more and more general, and art objects everywhere, in Europe at least, are all but alike. Nay, is it not a fact, and a right notable one, that there are what may be well termed "art centres,"—centres of art manufacture, which have been established for the express purpose of supplying generally the whole of Europe,—the world, indeed,—and its individual and separate nationalities, with art objects, and with things of every-day requirement, so decorated and ornamented as to suit, as it is thought, the special requirements, and art taste, and aspirations of those for whom the objects are manufactured? And, together with this, there is what may well be termed an all but universal idea and system of art teaching, thus compelling those who learn to imbibe like art-ideas and methods of work, all tending to the production of like "results."

And not only are the art-productions of each European centre, with each its separate nationality and language, getting to be more and more alike, and not at times to be distinguished the one from the other, but, what is more startling, there is the fact of the employment, by each nationality, more or less, of workmen foreign to it, from other and diverse nationalities, and it is beginning to be thought, by not a few, that this is a positive gain, and that the art-power of the time is increased by such method of work, and that, through it, a sort of general, and, so to phrase it, universal art-power, applicable generally and everywhere, must eventually and in time be created and become available. And no doubt this is so, as our schools of art prove, and as our periodical exhibitions of art products show. But whatever the advantage and the gain by such universal methods may be, and however systematised, and however perfect the results, of one thing we may be sure, that these results must needs be more or less alike and similar, and all but duplicates of each other, and that before such powerful and effective teaching, and uniformity of teaching, all "nationality" and almost individuality, must needs in time disappear. There may, as we say, be gain in all this, but there must be loss too, and a very great loss.

In the note to which we have referred, it is stated that a most determined resistance on the part of the Italian workmen was made to any interference with them, or to any attempt to add even but one more to their numbers. It would be not a little interesting to know whether this resistance to any addition being made to their numbers arose solely from this simple cause, or whether, in addition to this cause of alarm, there was not that of a desire to keep their nationality intact, and a determination not to admit a foreign art element or influence. The art they produced was Italian wholly, and must needs, as we may suppose, interest them as such, and the introduction of another style of art-handwriting may have been resented. Was this so? The English workman and artist may be, as he says, as good to the full as an artist-workman as those with whom he sought to ally himself, and this they may have been conscious of but it might have been curious to learn as to how far, if at all, they resented this intrusion of a foreign art element into their purely Italian art, and amidst their national way and method of producing it. That this would and must have been felt at divers periods of art history, there can be no doubt; and the interesting question hence here arises, does the Italian art workman of this present day feel this?

CASTLES OF THE EARLY ENGLISH PERIOD.

THE transition from the Norman to the Early English style, which in ecclesiastical architecture constitutes a period of great interest, is by no means, at least in England, so strongly marked in buildings of the military type. The rectangular and circular or polygonal keeps, with their Norman features, retained their hold upon English castle-builders through the reigns of Stephen and that of Henry II., 1135-1189, or for a century and a quarter from the Conquest, or even later. At Dover, the dog-tooth ornament and a bead moulding, combined with very decidedly Norman features, mark the transition period, as do the ornamental details of the rectangular keep of Helmsley, and the particulars of the shell-keeps of Tamworth and York. The later keeps are known by the increased depth of the pilasters, which become buttresses, as at Dover and Clun, and in the twelfth-century keep of Chambois (Orne); sometimes by their improved and fine-jointed ashlar, as at Hedingham; by a more frequent use of the stone of the district instead of that brought from Caen; by the presence of ribs upon the groins of the hip-vaulting of the galleries and mural chambers; by the use of nook-shafts at the exterior angles, as at Scarborough and Castle-Rising; and by the greater tendency to ornament about the rib bosses, door-cases, window recesses, and fire-places, and by the more or less Early English character of such ornamentation. The portcullis is perhaps less rare in the later keeps. There was, however, little change in the internal arrangement so long as the Norman outline was retained, and but little tendency, so far as the keep was concerned, towards flanking defences. Passive strength is still relied upon.

Little is known of the *castra adulterina*, of which so many score were constructed during the reign of Stephen, and destroyed by his successor. They could scarcely have been of the solidity of the Norman keeps, else their demolition would have been a more difficult task. They were probably either of timber, or mere walled inclosures of no great strength. Few, if any of them, represented the chief seats of large estates, and being built for the most part on new sites, the earthworks were inconsiderable, and where the works above ground were destroyed there was little left to show where was their site. Among the latest rectangular keeps should be mentioned the tower at Penhow, Monmouthshire, the cradle of the house of Seymour; and that of Fonmon, in Glamorgan, still inhabited. They are small, without pilasters, and with scarcely any Norman features, and belong to the Early English period, as, judging from its foundations laid open, and from some fragments dug up, several years ago, did the castle of Sully, near Cardiff, and probably that of Dunraven, in the same county, the remains of which are built into a later house.

By degrees, as the Norman towers and shell-keeps fell out of fashion, they were succeeded by towers of a cylindrical form, known as Donjons, and this change corresponds to the middle period of the Early English style in ecclesiastical architecture. Scientifically, in a military point of view, this was scarcely an advance, for the defenders of an isolated round tower could not concentrate their fire, and could only protect the foot of the wall by exposing themselves at its summit. On the other hand, with equal material, the round-tower was stronger, and more difficult to breach or to bring down by a mine. Also, it admitted of being vaulted in every story, and was thus more compact and less exposed than the rectangular keep to being set on fire, either from within or by balls projected upon its conical roof. Usually, however, in England, only the basement was vaulted, as at Bruuless. At Pembroke the great round tower is vaulted at its summit, as are some of the cylindrical towers in the *enceinte*; but it is possible that these elevated vaults may be additions. At Coningsborough the basement alone is vaulted, and the vault is entered by a ladder from an aperture in the centre of the dome, under which is the well; the basement, as in Norman and Early English towers generally, being used as a store-chamber, and seldom, if ever, as a prison. In fact, in a single tower, whether rectangular or cylindrical, intended by its passive strength to defy attacks and to wear out the patience of a blockading force, an ample store of provisions was of the first consequence, and to their storage all the spare space was necessarily devoted. In those days, when the keep was the citadel, and not unfrequently used as such, prisoners were not kept within its walls. Dungeons there were none, save in a very few exceptional cases, and the basement or ground-floor was invariably occupied as a magazine.

These donjons were usually entered at the first-floor level, either by an exterior stone stair, or by one of timber; or sometimes, as at Pembroke, by a drawbridge, which dropped upon a detached pier, whence an inclined plane or a flight of steps descended to the ground level. In their elevated entrance, and in some other respects, these donjons recall the isolated towers erected during the decline of the Roman Empire, of which a good example, but square, remains at Autun. There are only two instances in England of the application of a forebuilding to cover the entrance of these towers, but these, Chilham near Canterbury, and Orford in Norfolk, are late Norman, not Early English. Dolbadarn in North Wales, a rather later tower, but cylindrical, has an exterior stair of stone, which, however, may be an addition.

There were commonly three floors. The basement was for stores. The central floor contained the principal apartment, usually with a fire-place, and sometimes with mural chambers, one of which is almost always a garderobe. The flues of the fire-places and the shafts of the garderobes are often vertical, and contained within the wall. The upper floor, was either for the soldiery or for a bedroom for the lord. The walls are ordinarily 10 ft. to 12 ft. thick, and there is often a well stair, as at Skenfrith in Monmouthshire, from the first floor, leading to the upper chamber and the battlements. In some of the ruder towers, as in that near the church of Aghadoe, near Killarney, the ascent from the first floor is by narrow steps projecting from the interior face of the wall into the chamber. In the larger towers, as at Coucy, there is often a small chamber in the wall, over the main entrance, for the working of a portcullis. Now and then the staircase begins at the ground-level, ends at the first floor, and begins again at the opposite side, as in the rectangular keeps. Thus no one could leave his post on the battlements without the knowledge of the captain, who lived in the main chamber.

Where the cylindrical tower formed the donjon or keep, it was commonly placed within the area, as at Bruuless and Skenfrith. At Coningsborough it stands upon the outer wall, at Pembroke on the wall of the inner ward; but in neither case is there any communication between the tower and the rampart of the wall. At Coucy the tower stands on an inner wall, but is girt about with a low concentric wall covering the foundations. At Launceston the annular space thus created between the tower and the girdling wall was roofed over, and there is something similar round the tower of Penrice in Gower. At Tretower a round tower has been built within an older rectangular keep, and the space between roofed over. In these cases the outer wall was about half the height of the tower. At Lillebonne and Coucy the tower has its proper ditch, as at Caldecot in Monmouthshire.

Coningsborough on the Don is the most complete English example of the Early English or Transition Norman cylindrical keep. Pembroke, though rather later, and of far inferior workmanship, is also, in its proportions and dimensions, a very fine building. Launceston, Tretower, Penrice, Skenfrith, Bruuless, and Dolbadarn, are good examples, as are the Danes' tower at Waterford, and the small and rude, but very curious, tower at Aghadoe. At Nenagh also is a very fine tower, apparently of the Early English type. The round keep of Barnard Castle, though of nearly similar pattern, is of later date. At Whitchurch, near Cardiff, are, or recently were, the foundations of a detached round tower of considerable diameter, the base mouldings of which showed it to be of Early English date. At Caldecot, a fine old Bohun Castle, admirably described by Mr. Octavius Morgan, is a round tower, probably Early English, having a ditch of its own. This tower crowns a small and evidently artificial mound. It is now a mural tower upon the line of the outer wall, but it seems to have been cased, and the core is probably, or possibly, the keep of an earlier castle.

These English towers, though curious, are far inferior to those of the same period remaining in France, whether keeps such as Étampes, 1160, the plan of which is a quatrefoil; or Roche-Guyon, where one-half of the cylinder is absorbed in a triangular spur; or mural towers, as the King's Tower at Rouen, that at Carcassonne, and a specially fine one, lately restored, at Pierrefonds. The keep at Nuremberg is also a good example. The tower of the Louvre has long been destroyed, but its base was recently laid open, and found to contain two shafts, a well and a sewer.

Probably the round towers, or keeps, are the oldest examples of the form, but very soon afterwards they came into use in England and France as mural towers, flanking and strengthening the *enceinte* wall. They were especially used to cap an angle or to flank a gateway. There is an example of a round tower capping an angle, of this date, in the Tower of London, known as Bell Tower. Marten's Tower at Chepstow is a good example of a mural tower of the Early English period, having a fine oratory attached. Its interior is a complete cylinder, but the exterior, or gorge wall, seen within the court, is flat. At Rochester, the angle of the ward next the keep has a circular tower, or rather a buttress tower, as it is not higher than the curtain. In such positions their passive strength was a great advantage.

In the latter part of the twelfth and the beginning of the thirteenth centuries much was done to introduce domestic comfort into castles. Fireplaces, which in the Norman keeps are but recesses in the wall, often with a mere lateral orifice for a smoke-vent, as at Colchester and Rochester, are now adorned with hoods, often of stone, sometimes of wood and plaster, and the flues are capacious and calculated to carry off the smoke. The stone hoods are usually of excellent masonry, and, even when plain, of much elegance of design, resting upon

brackets, and these on clustered columns flanking the hearth. The vent or flue is often capped by a chimney-shaft and smoke lanthorn, such as may be seen at Grosmont and St. Briavels castles, or in the remains of the Priory at Abingdon. Where the hood was of wood or plaster, with a shaft of the same, or where there was an opening or louvre in the roof, all traces are, of course, gone, and thus is explained the absence of fireplaces in rooms evidently intended for ladies and persons of rank.

In the Norman keeps boarded floors were a necessity, and very ill-jointed and cold they no doubt were, but with the vault the floors were composed of beaten lime and sand. Garderobes continued to be frequent, both in mural chambers and on the battlements, and the shafts were usually vertical, and descended within the wall, having an outlet at the foot of it. The hall, chapel, and other buildings, placed usually in the inner ward, were more ornate than in the Norman period.

In addition to the flanking defence afforded by towers upon the line of the *enceinte* wall, there was in general use a contrivance called a "Brétasche." This was a gallery of timber running round the walls outside the battlements, and at their level, supported by struts resting upon corbels, and covered in with a sloping roof. Sometimes, in large towers, there were two tiers of these galleries, the upper projecting beyond the lower, and thus affording a very formidable defence. As these galleries concealed the top of the wall, this part was often left in a rude state, and now that the *brétasche* is gone, such towers, as at Caerphilly, have a very unfinished appearance. The *brétasche* was only put up when a siege was expected, and examples of it are very rare indeed, although it is evident in numerous instances that it was formerly in use. There remains a fragment of the actual *brétasche* over the Soissons gate of Coucy; and at Ledes, over the outer gate, is the place of its main beam. The tower of the Palazzo Vecchio at Florence shows by its lines of corbels that it was intended to carry a *brétasche*, and a door is seen, as at Norham, in the wall, which could only have opened upon a timber gallery. Château Gaillard, the work of Richard I., has what is not unlike a *brétasche*, executed in stone.

The best example in England of the kind of tower which succeeded to the rectangular and shell-keep of the Norman period is the keep of Coningsborough, which, though containing certain Norman ornaments and details, belongs to the Transition period. It stands on the summit of a natural hill, and forms a part of an earlier *enceinte* wall, which has been clumsily broken to admit it. The tower, about 70 ft. high, is cylindrical, about 50 ft. diameter at the base, and 40 ft. at the summit, but the cylinder is supported exteriorly by six buttresses of great breadth and bold projection. There is a basement domed over with a central hole above the well. The only entrance is in the first floor, about 12 ft. from the ground. The upper floors and the roof were of timber. The staircases are in the wall, winding with it. There are two garderobes, two fireplaces, no portcullis, and in the upper part of one of the buttresses is an oratory. The roof was a cone, but sprang from a ring wall, about 3 ft. within the battlement wall and the rampart walk. By this means the tower could be defended without a *brétasche*, which would not have been the case had the roof rested on the outer wall. A similar arrangement may be seen at Marten's Tower at Chepstow, and at Pembroke.

It is not, however, in England that the best examples of these Early English or Transition keeps are to be found. In rectangular and shell keeps England has some fine remains, but in France Philip Augustus carried the new style of building much further, and even now there remain keep towers of that time which have defied time and the madness of the Revolution, and still remain tolerably perfect. The greatest triumph of the period, in this case early in the thirteenth century, is the tower of Coucy, probably the finest military tower in Europe. It is the keep of a castle which is itself the citadel of a town, also strongly fortified. This wonderful work, a cylinder of fine masonry about 98 ft. in diameter, and rising clear and unbroken to 180 ft., was the work of Engerrand III., Sieur de Coucy, and the most powerful Baron of his age. The walls are of great thickness, and the basement and upper floors, three in number, were vaulted, each in twelve deep and pointed cells. A fosse, paved and walled, 20 ft. broad and 12 ft. deep, the counterscarp of which is raised as the wall of a *chemise*, surrounds the base, and protects it from the operations of the miner. A drawbridge, crossing this fosse, leads to the first floor of the tower by its only entrance, which is protected by a portcullis, an interior *meurtrière*, and a stout door. From the entrance passage a staircase ascends in the wall, at first direct, and afterwards as a turnpike, and supplies each floor, reaching finally the ramparts. The basement was the store, and above are state and other chambers. The well, of large size, is in the basement, and each floor has its fireplace and garderobe. The roof was conical, and rested upon an internal wall, outside of which was the rampart walk, protected by an unusually lofty parapet, surmounted by a heavy bold coping, and pierced by twenty-four doorways, intended to open into the timber *brétasche*, while between the doorways are twenty-four loops, intended to be used when the *brétasche* was not fixed. A curious evidence remains of the manner in which this tower was scaffolded. A double row of putlog holes are seen to wind round the tower spirally, in two parallel lines, showing that as the wall rose it was surrounded by a sloping roadway of timber, of which the main beams were thrust into the wall, and supported by struts, the lower ends of which rested upon blocks in the lower holes. A similar arrangement may be seen in the north-west tower of Harlech Castle, commencing at the top of the curtain-wall. So strong was Coucy keep that when, at the command of Mazarin, powder was exploded in its basement-chamber, and the vaultings throughout, thus lifted, fell, the cylinder, though cracked, was not thrown down. This noble example of a thirteenth-century tower has been successfully repaired by Viollet-le-Duc, who closed the fissure, and made the tower apparently as sound as ever.

Nor does Coucy, though the chief of the towers of the thirteenth century, stand alone in its magnificence. Issoudun, known as La Blanche Tour, is remarkable for the position of its entrance-door, and for its well-stair contained in the projecting spur; Tournebut, Cosson, Verneuil, Chinon, Villeneuve-le-Roi, Semur, Alluye, Bourbon-l'Archambault, and Châteaudun, are a few only of the round towers or donjons, scattered over France, and dating from the latter half of the twelfth and from the thirteenth century.

There is a peculiarity in these French towers unknown in England. Where, as at Château-Gaillard, they are exposed on one side to be battered, they are constructed with a projection forming a right-angled salient from the cylinder, which thus becomes keel or boat shaped in plan. This spur has a fine effect, and being usually solid, adds much to the strength of the tower. This projection, of which Roche-Guyon is a fine example, and which ascends the whole height of the tower, is very different from the spur-buttress, by which a round tower rises from a square base. This is especially common in Wales, and may be seen producing a good effect both at Chepstow and Goderich.

Of cylindrical keeps, either of early English or late Norman date, in England, may be mentioned Brunless, near Brecon; probably Caldecot, Monmouthshire; Coningsborough; Dolbadarn, in North Wales; Launceston; Pembroke; Penrice, Glamorganshire; Skenfrith, Monmouthshire; and Tretower, county Brecon. The round tower at Barnard-Castle, a very fine one, already mentioned, is later.

The reign of Henry III., 1216-1272, was long, and that prince was a munificent patron of art, and especially of architecture; nevertheless, and notwithstanding the internal dissensions of the period, the reign produced (excepting perhaps in South Wales) but few original castles, and those not remarkable for grandeur. The cause of this was that the country was already rather overfurnished with castles, so active had the Norman lords been during a century and a half, and the positions of the existing castles being well chosen, and their keeps of a substantial character, it was found better to add to them, when space was needed, rather than construct new ones in new positions. The itinerary of John shows that almost all the great castles of the country were even then built, and the use to which they were so frequently put may well have made the successors of that sovereign anxious rather to destroy than to build. Thus Bedford, a very early and very strong castle, was held by Hugh de Brèanté against the king in person, and was only taken by assault after a vigorous siege of two months, after which it was not only dismantled, but destroyed, its ditches filled up, and the materials of its walls and towers used for other constructions. Sometimes, however, where it was desirable, as in London or at Porchester, or Winchester, or Richmond, to retain the existing castle, either *enceinte* walls or more extended outworks were added, affording more accommodation for troops or for live stock for the garrison. Palisades gave place to walls, and mural towers and gatehouses, of large size and great strength, were added. Sometimes, as at the Tower of London, an outer ward, encircling the older building, was added; in other cases, as at Corfe, Chepstow, and Barnard Castle, the new ward was applied on one side, or at one end. In these augmented castles the keep was still treated as an interior citadel, a last resource or refuge, and was protected by one or two lines of wall, with mural towers, usually round or half round, and by gatehouses, composed of two round towers with the entrance between them, the new area within being proportioned to the importance of the place.

These composite structures are the earliest to which the term concentric is properly applicable. Where the keep is central, and the *enceinte* double, as at the Tower and Dover, the result is a very perfect example of the concentric type of castle, though of course the parts are of different dates. Of Kenilworth, and probably of Bridgnorth, the original arrangement was concentric, although the central part is a ward or walled enclosure, not a single isolated keep tower, which in these is worked into the line of the inner ward wall. As the outline of most castles was materially affected by the disposition of the ground, it is obvious that no classification as regards chronology can be based altogether upon the ground plan. At Alnwick, for example, the outline of which is probably Norman, and to some extent governed by the ground, the keep stands between two wards, and is the connecting part between them, and so at Chepstow and at Pickering; while at Richmond, also Norman, the arrangement is wholly different, as it is at Porchester, where Roman walls have been turned to account.

South Wales contains some castles which appear to have been altogether built, though possibly on old sites, in the reign of Henry III., as Cilgerran, Manorbeer, Grosmont, and Whitecastle. These, especially Whitecastle, are mere enclosures of irregular plan, within a strong curtain wall, supported by mural towers almost always round, and entered between two such towers as a gatehouse. The domestic buildings or lodgings, as the hall, sleeping-rooms, kitchen, offices, and stables, which in a regular English castle were of masonry, in these Border structures, such as Whitechurch, were partly of timber, with flat or moderately-sloping roofs, built against the walls of the area.

In the royal castles, and others the "capita" of estates and seats of the greater barons, great attention was paid to domestic comfort and splendour. The records contain many sheriffs' accounts for additions or repairs for domestic buildings within the castles, for painting the walls in fresco, or filling the windows with stained glass, all showing a vast growth in taste and luxury. More attention, indeed, was paid to these matters than to the military defences, for the castles in time of peace were allowed to fall into disrepair, and scarcely any garrisons were kept up. When a rebellion broke out, and the castles of a district were threatened, the patent and close rolls are filled with orders to the sheriffs, constables, and castellans, to supply timber, nails, lead, cordage, barrels of arrow-heads and cross-bow bolts, calthrops, bow-staves, and now and then military engines, which were collected from all quarters. All, however, was done hastily, and any masonry work erected under such circumstances is generally found to be of inferior quality, and in marked contrast to the masonry of churches and ecclesiastical buildings of the same period.

In the reign of Henry also began to be constructed fortified dwelling-houses, embattled and usually moated, but not regular castles. The invasion of the prerogative, under Stephen, led to its enforcement with strictness in the subsequent reigns, but as there were few new castles, it was chiefly in favour of fortified houses that the *licentia kernellare* was applied for and granted. The earliest extant licence of this character dates from this reign, and about a score altogether appear to have been issued by Henry. Of these, six only were applied for by considerable barons, and in only two cases for castles of consequence, namely, Dudley and Belvoir.

G. T. C.

ENTRENCHMENTS OF THE YORKSHIRE WOLDS.

IN the Anthropological Department, British Association meeting at York, General Pitt-Rivers, F.R.S., read a paper on "The Entrenchments of the Yorkshire Wolds and the Excavations in the Earthwork called Danes' Dyke at Flamborough." The district consists of four patches of high ground separated from each other, and bounded by five principal valleys. Assuming most of the low ground to have been occupied in prehistoric times by marsh and jungle, there would remain only the plateau lands on the hills for the inhabitants to live upon, and here, as might be expected, we find the ground covered with their remains. Flamborough Head and promontory must, of course, have formed the base of operations for warlike purposes in any case, whether of an invading or retreating force. In the former case it would be the first, and in the latter the last, point occupied by any people at war with the inhabitants of the interior. The high cliffs precluding all possibility of an attack by the sea, and leaving only the land side to be attended to, they would naturally expect to find an entrenchment facing westward, and occupying the first suitable position westward. Such an entrenchment they found in what was commonly known as Danes' Dyke, a misnomer, as he would show. The Dyke runs north and south a distance of two miles and a half from sea cliff to sea cliff, and at a distance of three miles from the centre of it to the point of the promontory. It has a ditch on the west or inland side, showing that the enemy was expected from that quarter. It is judiciously chosen, and on the whole commands an extensive view of the country for some distance to the westward. There are twelve gaps through it, some of which are no doubt modern. A small stream coming from the north runs through the entrenchment, affording a supply of water to the defenders. The entrenchment is of nearly uniform height all along, being about 18 ft. above the level of the ground, and having a ditch 60 ft. wide at the outside. Of the defensive character of the entrenchment there could not be the slightest doubt, and it was a work of great strength, probably surmounted originally by a palisade, and implying a large and well-disciplined force for the construction and defence of it. With the exception of two entrenchments between the north end of Danes' Dyke and Speeton, which run from the edge of the cliff southward, and the ends of what have been ploughed out of cultivation, nothing of any consequence occurs in the way of military defence until the great position at the ancient village of Argam. On the north wold an entrenchment runs along the top of the escarpment of the Derwent valley. It originally extended from Hunmanly on the east to above Heslerton on the west, and guarded the north wold hills from an attack from the Derwent valley. A branch from the dyke defends the wold hills from any attack by the north-west up the valley at Wintringham. Behind and parallel to this, two miles in the rear, are double dykes running between Kirby-Grydalythe and Butterwick, also occupying a strong position on the hills toward the north-west. Behind this again, a mile and a half in the rear, are other dykes parallel to the last, running between Sledmere and the hill west of Hewing, also occupying a position for defence against the north-west. Besides these the north wolds are covered with numerous smaller entrenchments. After describing what he considered as the most instructive portion of the whole district, the oolite range to the north of the Derwent valley, which included a system of defence persistently adopted in all prehistoric works in this country, whether camps or dykes, the author described how, with the kind permission of Messrs. Dormer, to whom the ground belongs, he commenced an excavation at the Danes' Dyke, on October 13th, 1879. A number of flints and flint flakes were found, affording evidence that the defenders of the earthwork used flint, and consequently that the work itself was not later than the bronze period, and was, in fact, of the same age as the tumuli of the Yorkshire wolds. They were narrowed to the opinion that the invaders of Flamborough, if invaders they were, were the same people who landed on the south and south-east coast of England, or else that these dykes belonged to the people of the country, who, having imported the bronze culture from elsewhere, were driven to the coast by another and more powerful race who occupied the interior, and that these defences were associated with their last occupation of the soil of Yorkshire. Further than that he did not venture to particularise. He trusted it would be admitted that the excavations and observations he had made landed them somewhat further on the road to knowledge than they were before. Notwithstanding the traditions which connected the place with the Danes, and the prevalence of a Danish element in the population of this country, the traces of which had been so well brought out by Mr. Atkinson in his history of Cleveland, this ground was the scene of operations of a very much earlier people, a people who, though ruder in their culture, were much their superiors in the art of war, formidable in their means of offence and defence, and in the discipline necessary to construct the great works he had been speaking of.

NEW BOARD SCHOOL, OBAN-STREET, TOWER HAMLETS.

AMONG the more recent schools erected by the School Board for London from the designs of Mr. Edward Robert Robson, F.S.A., several changes have become apparent. One is a tendency to increase the size of each school, so that it shall suffice for a larger district and greater number of children, as well as be more economical in management. The question is whether they are not, in some instances, even too large. Another is the adoption of a unit of sixty for class-rooms, capable (where there is no hall) of subdivision into two thirties for the use of pupil teachers. A third is a closer attempt to light as many rooms as possible from the left of the pupil, as is the later German practice. These two last are conflicting in principle and often irreconcileable.

One of the last instances exemplifying these changes is that of the Oban-street schools, Bromley-by-Bow, now in course of erection, of which our illustrations show the arrangement. The site of the building is peculiar, having one frontage on the level of the surrounding streets, and the opposite frontage, at a much higher level, towards the canal towing-path. Taking advantage of this circumstance, Mr. Robson has raised the whole building on arches, thus forming covered playgrounds underneath, the infants' department being approached by inclined planes. The plan of the school, with its great hall, naturally suggests a Gothic treatment somewhat after the type of the Belgian trade-halls. But the *raison d'être* of School Boards is not in harmony with Gothic, and the result is a style of somewhat curious blending, the Gothic *motif* mingling with the usual treatment which Mr. Robson has rendered familiar in his schools.

It will be noticed that there are two staircases for each department. In each case the height of the schoolroom is divided into two floors of mezzanine, approached from the staircase landings, and utilised as cloakrooms and teacher's rooms. The accommodation is for 420 boys, 420 girls, and 560 infants; or a total of 1,400 children.

The building will be warmed by steam-radiators on Leede's low-pressure system of 5 lb. to the inch, supplemented by open fires in some of the class-rooms.

The tender for the erection of the building by Mr. S. J. Jerrard, of Lewisham, amounts to 18,244*l*.

The number of new schools erected by the School Board (exclusive of enlargements) now reaches the remarkable total of 270.

HIGH SCHOOL FOR GIRLS, DOVER-STREET, MANCHESTER.

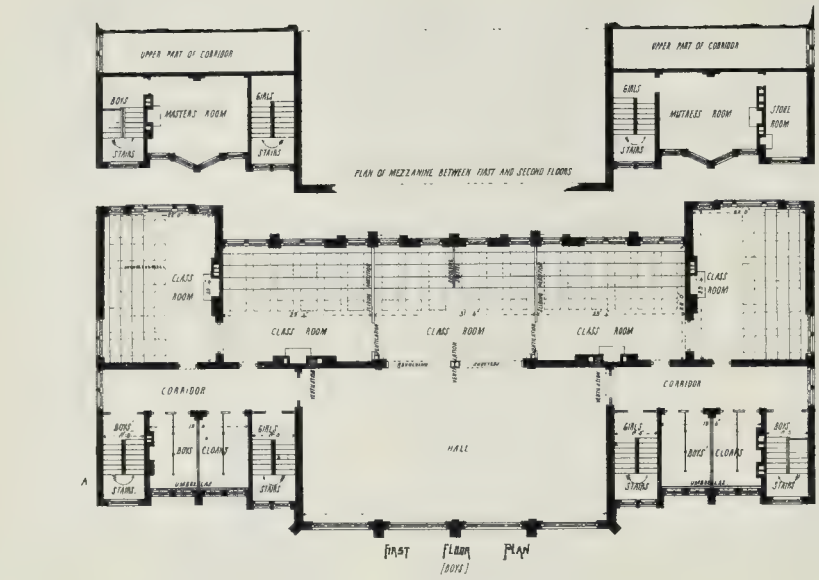
THIS building, which is almost ready for occupation, has been erected under the direction of Messrs. Mills & Murgatroyd, architects, Manchester, on a site containing about 3,500 square yards of land, in Dover-street, Chorlton-on-Medlock. The school has been carried on most successfully for several years, but the premises formerly occupied by it being inadequate for the purpose, larger and suitably arranged premises, of which our illustration shows the principal front, have been erected. The exterior is faced with pressed bricks, with moulded jambs and arches, while red terra-cotta has been largely employed for sills, strings, water tables, and weatherings; this material has been supplied by Messrs. Johnson & Co., of Keymer Junction, Sussex.

The frontage is 146 ft., and the buildings extend to the rear 160 ft. On the left of the entrance are committee-room and teachers' common room on the ground-floor; museum and library on the first floor; and some of the principal class-rooms above. On the right is the dining-hall, 72 ft. by 31 ft., on the ground-floor, and the lecture-room is above it, covering the same area, but having a lofty open-timbered roof. From the entrance a wide corridor extends to the rear, having on one side class-rooms, and on the other dressing-rooms, &c., the water-closets being in all instances separated from the dressing-rooms by an intervening lobby with cross ventilation. The class-rooms number in all twenty-two, and will accommodate some 550 pupils with an allowance of about 17½ square feet of floor space each. There are, besides, a well-lighted drawing-room, 110 ft. long, a laboratory and chemical lecture-room, large covered play-room, and an excellent cloakroom, fitted up with drying-closet, &c., in which wet garments may be satisfactorily dried during the school hours. Kitchens, &c., are placed near the dining-room, but as the establishment is exclusively a day-school, no sleeping-accommodation has been provided. The committee, however, which, by the way, we may mention is composed of both ladies and gentlemen of position in Manchester, possesses some 1,500 square yards of land to the left of our view, on which any extension that may be desirable can hereafter be carried out. Messrs. W. Southern & Sons, of Salford, were the builders.

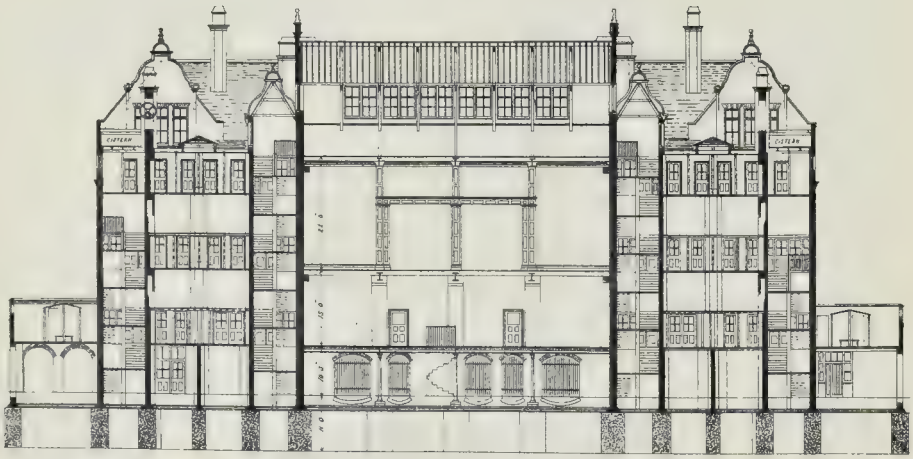
DESIGNS FOR DATE TABLETS.

THESE designs for carved date tablets could be used for stone, brick, terra-cotta, or wood, with more or less of detail, according to the material in which they might be carried out. Of course, it is understood that the highest finish would be given when used in wood, and the drawings published are finished up for their use in that material, which, when in position, will be for interior work, and therefore not only nearer the eye, but removed from the damaging influence of the elements. In this case, as they would be chiefly used for small panels in furniture, over mantels, doors, &c., they would seldom be required larger than 6 in. or 8 in., and for general use would probably be of smaller dimensions. But for stone and brick they would very seldom be less than 10 in. or 12 in., and require much less detail, being carried out in a bold and free handling. As they would be seen from a distance, all delicate work would be lost, and, moreover, soon rounded off, by exposure to the changes of our climate.

Some short time ago, while passing a row of well-built detached houses in the modern Queen Anne style, it was seen that the date tablets on each house, although well carved and placed in a most conspicuous position, were all alike; and the question arose where the advantage lay in repeating this hand-work.



We talk a great deal of the care and spirit infused into the old work, and, while condemning our own workers of to-day, seem to forget that those old workers repeated very little in comparison to the change of design they carried out; while, on the contrary, it is quite the exception for the mason or smith of our time to have anything to do but a constant repetition of a few accepted forms. Can we, therefore, justly complain if he becomes an indifferent machine?



Mr. Lewis F. Day wrote some time ago an interesting article, showing the reasons why a man's house is less his home than it should be. He confined himself to interior decorations and their influences, but we cannot help thinking that our architects can help us quite as much outside as we can help ourselves inside in making our houses our homes, and creating proper pride of possession. If we seek a reason, and one quite outside the question of art or good taste, which are synonymous, is it not a very pardonable vanity in Brown to wish his house somewhat different to Smith's?—a desire for it to possess some individuality, trifling though it may be?

As regards the architectural fabric itself, the actual building, one must perforce accept the inevitable with the best grace possible, if we do not possess the means of indulging in a house built after our own heart; but there are little accessories which go to complete a building, and give it character, as in the fan-light, wherein thought of the future occupier might

DESIGNS FOR DATE TABLETS.—By Geo. Chas. Haite.

A STREET IN ROTHENBURG, GERMANY.

well be considered. The breaking-up of the door, the date tablet, the small stained-glass window over the porch, the grille in the gate, &c., these need not surely be all alike, and thereby the end and aim almost of their adoption defeated. The expense entailed would be small, and chiefly for the designs.

A STREET IN ROTHENBURG, GERMANY.

IN the references we frequently have had occasion to make to the very interesting ancient town of Rothenburg, we have chiefly confined our remarks to the general aspect of the place, to the most perfect system of ancient fortification to be seen there, and to the churches. We now propose to say a few words about the domestic architecture.

Although Rothenburg does not present to our notice any very early example of civil or domestic work, yet the specimens of the latter are very numerous, and far from uninteresting. The illustration which we give of a street in the town includes several interesting peculiarities. The treatment of the lofty gable of the house shows that the roof has been intended for a store-place or warehouse, and the doors for the admission of goods are treated in a remarkably ornate manner. We find amongst the enrichments that bold treatment of the pelleted cable moulding which is one of those singular recollections of Romanesque detail never quite abandoned by the Germans. We also see the interpenetrating cusps, a feature peculiar to late German work. The charming little angle oriel, or, as the Germans call it, "esker," at first appearance seems to belong to a somewhat later period, but in all probability it is of the same date as the rest of the building. It is very interesting from the fact of its retaining its original glazing and tiled roof. The tiles are glazed, and are green, yellow, and red in colour. There is a somewhat marked absence of sculpture about the old houses in Rothenburg, which will be at once noticed in the example we give. This probably arose from the fact that the town, which was one of the "Cities of the Empire," adopted the faith of "the Augsburg Confession" at an early period.

The apse shown in the distance in our view is the western choir of the great Church of St. James. This choir is raised up many feet above the nave of the church, and forms a kind of western gallery. At present it is used as an organ gallery, but probably before the Reformation it was furnished with regular choir-stalls, with an altar, arranged basilica fashion, as we see in the cathedrals of Augsburg and Naunberg. These western choirs are peculiar to Germany, and probably led to the western choirs and organ galleries which became common over the whole of Northern Europe in the seventeenth and eighteenth centuries.

SANITARY PROGRESS.

SIR,—I should be glad if, for the information of those engaged in sanitary works, you could find room for this revised copy of a letter of mine showing some of the economical results obtained by them:—

The extent of the excellent papers, and of the discourses on purely medical or curative science at the International Medical Congress, precluded more than very slight attention being given to sanitative or preventive science, and prevented a notice of the means of the reduction of a percentage of sickness or death-rate by it, or by curative science. Since the congress was held the report of the Local Government Board has appeared, and contains a statement of the progress of sanitary work in England and Wales, to which public attention may now be well directed both in justice to the subject and to the services of the new local health officers appointed, and acting, as yet, with very imperfect attributions and functions. The statement of the report is as follows:—

"Before concluding the part of our report which relates to sanitary administration, it may be useful to draw attention to the annual death-rate for some years past as indicating the effect which recent sanitary measures would appear to have had upon the public health.

The following table shows the death-rate for each of the four last decennial periods:—

England and Wales.

Annual Death-rate per 1,000.	1841-50.	1851-60.	1861-70.	1871-80.
All causes.....	22·4	22·2	22·5	21·5
Seven zymotic diseases	—	4·11	4·14	3·36
Fever.....	—	0·91	0·88	0·49

From the above figures it will be seen that, speaking generally, the death-rate of the country remained stationary from 1840 to 1870, but that in the period 1871–80 it fell from 22·5 (of the previous decade) to 21·5, a reduction equivalent to nearly 4½ per cent. It may, therefore, be roughly estimated that about a quarter of a million of persons were saved from death in the ten years 1871–80, who would have died if the death-rate had been the same as in the previous thirty years. If twelve cases of serious but non-fatal illness be reckoned for every death, it follows that about 3,000,000 persons, or over one-ninth of the whole population, have been saved from a sick bed by some influences at work in the past decade, which had not been in operation previously. The case, indeed, is still stronger than this. The death-rate of rural districts is habitually lower than that of urban districts; and as the population is steadily concentrating itself, more and more, into the towns, the death-rate of the whole country would tend to increase, if the other circumstances affecting it remained the same. When we find that this tendency has been so much more than merely counteracted, it becomes interesting to see where the gain has been; and to endeavour to trace some of the causes to which it may be due.

Comparing, then, 1861–70 with 1871–80, it will be seen from the foregoing figures, that of the entire reduction of 1·0 in the death-rate, more than three-quarters (4·14—3·36=0·78) comes under the head of 'The Seven Zymotic Diseases'; of the diseases, that is, which are most influenced by sanitary improvements, and most amenable to control by the action of sanitary authorities. And of this three-quarters just half (0·88—0·49=0·39), or three-eighths of the entire reduction, is in 'Fever,'—the disease which, more than any other, shows itself in connexion with such faults of drainage, of water supply, and of filth accumulation, as it is within the province of good sanitary administration to remove.

It is particularly significant that, since the year 1870, when the fever death-rate was 0·80 per 1,000, it has fallen pretty steadily, year by year, as follows, down to 0·32 in 1880:—

1871.....	·70	1876.....	·44
1872.....	·61	1877.....	·41
1874.....	·53	1878.....	·42
1874.....	·59	1879.....	·31
1875.....	·55	1880.....	·32

Thus in the five years, 1871-5, the fever death-rate was 0·61; in the five years 1876-80 it was 0·38."

During the decade from 1861 to 1870, there appeared to be no gain from the outlay on sanitary works or on sanitary service in England and Wales; but since then the service appears to have made an effective start, and the pecuniary gain may be thus stated:—Under the inquiry as to interments, the cost of funerals,—all round,—was ascertained to be 5*l.* each. The gain under that head will, therefore, be about one million by the quarter of a million of funerals saved during the last decade. The direct cost of sickness has been estimated at about 1*l.* per case. The gain under that head during the decade will, therefore, amount to about three millions; a gain, that is to say, of medical treatment and other expenses. But the gain to the wage classes, from the saving of lost labour, will have been far greater. Dr. James Watts, who has had great experience in friendly societies, states the average loss of working time at two working weeks and a half per member between twenty-one and seventy years of age, and he estimates the total loss to the wage classes, by the loss of work through sickness, at upwards of thirteen millions per annum. The gain derivable from sanitation may be further illustrated from its advance in military service. The first British army went out to the Crimea under the established curative or medical service, and it was lost. Sanitary Commissioners, trained in service under the first General Board of Health, were then sent out to reform the condition of hospitals and camp, and within three months reduced the sickness and mortality from a plague-rate down to an ordinary standard of health, and by the end of the summer of 1855, to a rate lower than that of the best hospitals at home; and the War Minister declared in Parliament that by the application of their science the second army had been saved. Since then, the Army Medical Department has applied extended sanitary operations. Their exercise under great difficulties is best shown in India. Formerly the death-rate in the Indian army was 69 per 1,000 per annum. The average mortality from 1869 to 1878 was only 20·41. There was, therefore, a gain of 48·59 per 1,000; or, on the present force out there, a gain of 2,350 men. The death-rate of the army at home was formerly 18 per 1,000. In the year 1879 it was 7·55, being a gain of 10·55 per 1,000. As the strength of the army in 1879 was 80,700, the gain was 843 per annum. The total gain to the army in India and the army at home, and the rest of the army, will be 3,443 men per annum. As each soldier is estimated at 100*l.*, this represents in money value 344,000*l.*, or more than a third of a million. It is not very easy to get at the real amount of the sickness, but the total gain, including the diminished death-rate, is considered to be under-rated at half a million per annum.

The total number of men killed on the battle-field and on the deck, including those killed at Waterloo, Trafalgar, and the most severe battles during the twenty-two years' war, was, according to the Army returns, 19,796. The lives saved from premature destruction by the civil sanitary service, during each of the ten years of the decade, was 25,000. The wounded during the twenty-two years' war were 79,709; but, taking a serious sickness as equivalent to a wound, the achievement of the sanitary service has been, during the same period, some three millions of cases saved by the civil sanitary service. The deaths by steam explosions, in mines and on railways, amount to about five thousand annually, but the lives saved by the civil sanitary service in England and Wales are five-fold greater than the lives thus destroyed by civil accidental violence. A reduction of the death-rate by 4½ per cent. is only an instalment of sanitary progress. Thus, in the instance of Croydon, visited by the delegates of the Congress, the death-rate has been reduced from 25 to 16 per 1,000, chiefly by the methods introduced by the first General Board of Health, by which spring supplies of pure water are carried into the houses, and the fouled water carried at once out of the houses and out of the town, by one Local Board authority, while all putrescible matter, instead of remaining for months and years in conditions of putrefaction, is undecomposed, and flows upon the land within two hours. So in Salisbury, Leamington, and a number of other places. At Croydon, it has been stated by Dr. Alfred Carpenter that, by complete sanitation, the death-rate might be reduced to 10 in a thousand. In the metropolis the death-rates amongst the wage classes in their common dwellings is upwards of 30 per 1,000. In the model dwellings in London, it is, however, about 16 or 17, even with surrounding deteriorating conditions. On the demonstrations of various model instances, it may be held that the reduction of the general death-rate by 4½ per cent., as reported, satisfactory as this is, cannot be considered more than one-third of the results obtainable by advanced sanitary administration and further sanitary works. The pain and misery, and the social disorder, occasioned by excessive sickness and premature mortality, are generally beyond pecuniary estimation. Such estimates as those given serve to show the money loss incurred, by inattention to the continuance of preventible physical evils.

EDWIN CHADWICK.

THE NEW INFIRMARY AT BOLTON.

THE new Infirmary at Bolton, opened on the 5th inst. by the Earl of Bradford, is at present the scene of an important exhibition of fine art. On the occasion of the opening, Mr. T. H. Winder (one of the hon. secretaries) submitted a report showing the origin and progress of the scheme for the erection of the new buildings. Practically the scheme originated in March, 1879, when, at a meeting of the subscribers, the Rev. Canon Powell intimated that he was authorised by a gentleman who desired his name to be kept secret to offer 5,000*l.* towards the endowment of a children's ward in connexion with a new infirmary. The anonymous donor proved to be Dr. S. T. Chadwick. At the same meeting another munificent contribution of 5,000*l.* was offered by the firm of Messrs. John Musgrave & Sons, of which the present mayor is the head. The old infirmary, in Nelson-square, was partially erected in 1824, at a cost of 1,300*l.* In 1838 and 1864 it was enlarged at considerable cost, the most recent of these additions being the construction of another story. Originally the institution was purely a dispensary, but from 1838 the institution included in its benevolent operations the purposes of an infirmary as well as a dispensary. As the old infirmary had been known for many years to be inadequate for the needs of the town and district, it was decided in 1876 to venture upon the establishment of a new infirmary and dispensary. A site forming part of the Bridge House Estate, adjoining the public park, and containing about 23,300 square yards of land belonging to the Ecclesiastical Commissioners and the Earl of Bradford, was secured on favourable terms, and competitive designs were obtained and exhibited to the general public. The committee submitted the designs to the judgment of Mr. Charles Barry, the then President of the Institute of British Architects, who recommended the first premium to be awarded to Mr. R. K. Freeman, of Bolton and Derby, who was accordingly selected as the architect of the new infirmary. The private donations, paid or promised, obtained through the instrumentality of the general committee, from the gentry and tradesmen, including about 7,300*l.* on endowment account, amount to upwards of 33,000*l.*, whilst by the devoted labours of the working men's committee, upwards of 1,300*l.* has been realised from the operative classes towards the new institution, in addition to 676*l.* produced by the Hospital Saturday collections in May last towards the working expenses of the infirmary. In May, 1880, the late Mr. Selim Rothwell suggested to the New Infirmary building committee the advisability of holding an exhibition of works of art in the new institution and in aid thereof; similar exhibitions in aid of the dispensary in 1850 having been very successful. Mr. Rothwell pleaded earnestly for a repetition of the experiment on an enlarged scale, and his proposal having been favourably entertained, a fine art committee was constituted. The committee commenced their labours by securing the patronage of members of the nobility, besides the gentry of the town and neighbourhood, and in order to establish a feeling of security and provide against any possible loss, a guarantee fund of nearly 2,500*l.* was subscribed for by those interested in the movement. The work of soliciting loans of pictures from collectors and artists then commenced in earnest. At first the promises of support were tardily given, but by degrees, through the constant exertions of Mr. Rothwell and several members of the fine-art committee, the numbers gradually increased until the middle of July, when upwards of 1,000 were entered as ready to be delivered to the exhibition committee. The work of collecting commenced on or about the 28th of July last, and by the 8th of August so many paintings had arrived that the committee determined to commence the selection and hanging at once. The collection obtained consists of about 1,600 paintings,

etchings, engravings, pieces of sculpture, and bronzes, which have been hung and arranged in thirty-one rooms and five corridors, and although some of the rooms are small and others not well lighted or adapted for such an exhibition, it is believed that on the whole the most has been made of the resources of the building. In addition to the above, the committee have been successful in obtaining the loan of collections of art pottery, coins, ancient armour, and a splendid collection of articles contributed by Messrs. Elkington & Co. The Science and Art Department, South Kensington, have also lent a valuable and interesting collection of objects of art in six separate cases, containing specimens of enamels, porcelain, carvings in wood and ivory, and a variety of Indian and Spanish textile fabrics. The committee have been successful in obtaining probably the best collection that has been exhibited in the neighbourhood since the memorable Art Treasures Exhibition in Manchester in 1857. It is to be hoped that it will not only be a pecuniary success, and so of help to the Infirmary, but that it may prove of lasting benefit in the development of a more appreciative taste for art.

THE PATENT LAWS.

THE SOCIETY OF ARTS' PATENT BILL.

Sir Frederick J. Bramwell, F.R.S., brought forward this subject at York. He said, after giving a history of the Bill,—The need of a patentee in the development of an invention was the first point the committee kept before them. The second point the committee had in view was that, so far as possible, the connexion between lawyers and patents should be severed. There can, I think, be little doubt that whether in regard to the original granting of patents, or in regard to their amendment, or in regard to the trial of patent actions, lawyers are the persons least adapted to perform these functions properly. No one entertains a more sincere respect than I do for the Bench and the Bar of England, and I wish, in the interests of that respect, to see them discharged of functions which most certainly they ought never to have had thrust upon them. Fortunately, having regard to the magnitude of the transactions involved in patent matters, there is but very little patent litigation. In the year 1874 it was ascertained for me that there were, upon an average, only nine patent actions which went so far as to be heard by a Court of First Instance in each year, and I have no reason to suppose that that number has materially increased, if, indeed, it has increased at all. But with respect to the few actions that are tried, a very considerable part of the expense arises from the elaborate models which are needed to instruct counsel upon the subject, who themselves have to inform both the court and also the jury, where there is one. And further, commonly, notwithstanding all the expense that has been gone to, and the pains that have been taken, the litigants have the chagrin of seeing that they have not been successful in making themselves understood either by the court or the jury, or, it may be, not even by their own counsel. The first proposition of the Bill is that there should be appointed, in lieu of the present Commissioners, who are all legal officials, a body of commissioners, one of whom should be well acquainted with engineering, one with chemistry, and one with law. Power is given to the commissioners, with the approval of the Treasury, to appoint the needful staff. It is intended that these commissioners should be the persons to grant patents, after a slight examination by examiners, not as to novelty, not as to utility, not as to sufficiency of invention, but simply to ensure that the necessary forms are complied with, and that a sufficient description is given. The commissioners, also, are those who would hear opposition, which it is proposed to confine to those persons who allege that the invention has been fraudulently obtained from them. They are also those who would consider as to amendments, and as to prolongations; and it is intended that both amendments and prolongations should be made more easy than they are at present. And, finally, it is the commissioners who would hear patent causes. This remitting to the commissioners of the trial of patent causes, probably is the most thorough change made by the Bill. Among the other provisions, the procedure has been modified, with the object of helping the patentee to obtain his patent more easily than at present, and more cheaply, and also with the object of rendering the patent more secure when he has once obtained it. The committee who framed the Society of Arts' Bill are of opinion that it is contrary to the interests of the public that a patentee should be deprived of his invention by what, after all, are technicalities. Further, it is a very common thing for a patentee to obtain provisional protection, and having done so, either through being too much occupied with other matters, or through being incompetent to develop his own idea, to abandon the further proceeding with the patent, and to allow his provisional protection to lapse, and thereupon the provisional specification is made public. I believe I am right in saying that something like 30 per cent. to 40 per cent. of all the inventions for which provisional protection is obtained do not go beyond that stage. The result is that there is made public, legally speaking, a mass of crude and undigested matter, always useless to the manufacturer, but commonly destructive of the novelty of a patent which might come afterwards and be fully worked out by an inventor. The committee propose that the provisional specification should be a merely temporary document, that it should never be made public, so that whether a patent be granted, or whether the provisional protection be suffered to lapse, the document should be destroyed. Similarly, it appeared to the committee that it was inexpedient a patent should be rendered invalid by any dormant publication, such as a book in the British Museum, and therefore they propose that unless an invention can be proved to have been in use within thirty years, no mere publication, unaccompanied by use, should be considered an anticipation of a patent. With respect to the term of a patent, it will be seen that the committee suggest the American term of seventeen years, coupled with the power of prolongation for a further eleven years. The term of seventeen years has been taken, coupled with this power, in preference to the term of twenty-one years proposed in the Government Bill of 1879, unaccompanied by prolongation, as the committee deemed that seventeen years, if the patent was successful, would afford the patentee sufficient remuneration, and also that having once established a body competent to deal with patent matters, there would no longer remain the difficulty of obtaining satisfactory decisions in cases of prolongation. The scale of fees proposed in order to obtain a patent is that of the Government Bill of 1879, and, as regards the subsequent payments, is practically the same as was proposed in that Bill.

Sir Antonio Brady, president of the Inventors' Institute, said that in his opinion the Society of Arts had done a most excellent work in bringing forward this Bill. He considered that taxation ought to be general, and that the brain-power upon which rested the prosperity and industry of the country should not be overtaxed. The Patent Law of America should be more their guide, and the Office should be made to render assistance to inventors. At present the register was so imperfectly kept that there was a difficulty in ascertaining when inventions had been patented, and provision ought to be made for preventing inventors running their heads together and going to law. If the proposed Bill were passed it would be impossible for two men to get a patent for the same invention in one day. The Bill was one that would recommend itself to the Inventors' Institute, and he should avail himself of an early opportunity of asking them to take it into their consideration and give it their support. The Society of Arts had done a marvellously good thing in bringing forward this Patent Bill. It is a mistake to think, as some people did, that patents were monopolies. He considered the country was very much indebted to Dr. Siemens for bringing his inventions over here. Although the patent laws of England gave more encouragement and aid to inventors than those of Germany, still they required much alteration. In America a patent was in reality property, but here it was a licence to go to law. In this respect he did not see why it should be different to the copyright law. With regard to the duration of the term of a patent, he did not see why it should not be twenty-one instead of seventeen years. If the Bill became law it would give a great impetus to the trade of this country. He thought the attention of the committee might be called with advantage to the desirability of reducing the fees so as to bring them within the limits of the working man.

Dr. Siemens said the Bill was the result of careful consideration and discussion by the committee, of which Sir F. Bramwell was the chairman, and he thought the best thing would be to take it *en bloc* rather than for the meeting to suggest any minor alterations.

THE SAVOY THEATRE.

This theatre, which is advertised to open on Monday, October 3rd, has been erected for Mr. D'Oyly Carte from the designs and under the direction of Mr. C. J. Phipps, F.S.A., architect of the Gaiety, the Haymarket, Princess's, and other theatres. It is situated on the west side of Beaufort Buildings, Strand, and occupies a site absolutely isolated on all four sides, thus affording free and expeditious entrance and exit for all classes of the public. The entrances are thus distributed, and are arranged so as to utilise the peculiar levels of the site.

For the stalls and dress-circle, and for all persons coming in carriages, the entrances are in Somerset-street, just off the Victoria-embankment. The pit is also entered here, and there is an entrance to the upper circle; the audience for both these latter parts can come direct from the Strand, by a short flight of steps adjoining Beaufort House. In Beaufort Buildings also is an entrance to, and on a level with, the upper circle. The entrances before referred to from the Embankment are on a level with the dress circle, and a few steps lead down to the stalls and pit.

The gallery is entered from Carting-lane, a street in a direct line from the Embankment to the Strand. The royal entrance is at the angle of Somerset-street and Carting-lane. The stage entrance is in Herbert's-passage. The box-office for booking seats during the day is situate close to the Strand, at the angle of the Beaufort-buildings frontage. The manager's offices are also entered from Beaufort-buildings.

The theatre is approached from Somerset-street through a semicircular vestibule, paved with black and white marble, in which are the offices for booking and obtaining seats in the evening. Doorways immediately opposite the entrances lead to the dress-circle corridor, out of which wide staircases will be found on both sides of the theatre leading to the stalls. From this vestibule are also means of communicating by an ascending staircase with the upper circle, and by pass doors to the pit staircase.

All the entrances, passages, and staircases are of fire-resisting materials; the flights of stairs are supported at each end by solid brick walls, and each staircase has a handrail on each side. There is no part of the theatre that has not two means of both ingress and egress, and the stage is separated from the auditory by a solid brick wall taken up completely through the roof. Water laid on from the high-pressure mains is in several parts of the theatre, and every possible means has been taken to ensure both the comfort and safety of the audience.

On the floor below the vestibule is a large refreshment-saloon for the pit, and contiguous to it a smoking room opening out of the stalls corridor, with a separate boudoir lounge for ladies. There are also refreshment-saloons on the upper floors of the theatre, for both the upper-circle and the gallery, with all necessary retiring and cloak rooms.

The auditory is thus arranged:—On each side of the stage opening (which is 30 ft. wide by 32 ft. high) are three private boxes on each of the three levels; these are divided by partitions and ornamental pillars, and are surmounted by an arch spanning the whole width of the proscenium, springing from a cornice on a level with the gallery front. These boxes are upholstered in hangings of gold-coloured embossed satin. The orchestra is in front of the stage, and is of sufficient capacity for a full band of musicians.

There are nine rows of stalls on the level of the orchestra, seated to hold 150 persons in arm-chairs, with ample space allowed for passing between the several rows, and wide unimpeded gangways on each side to the entrance-passages. Behind the stalls are six rows of pit-seats, calculated to seat 250 persons, with a spacious open corridor behind, for standing and promenading. Above the pit, but at sufficient height to allow of persons at the very back seeing the full height of the scenery, is the dress-circle of six rows of seats, with arm-chairs for 160 persons. There are no pillars of any kind in the dress-circle, so that a clear unobstructed view of the stage is obtained from every seat. Above

the dress-circle, but receding some 9 ft. back from it, is the upper circle, seated to accommodate 160 persons in five rows. The amphitheatre and gallery recede 5 ft. behind the upper circle, and will seat 400 to 500 persons in eight rows. In each tier the balcony-front takes the form of a horseshoe, that being considered by the architect the best adapted for perfect sight of the stage.

The ornamentation of these several balcony fronts is Renaissance in character, and is elaborately moulded and enriched with the figures and foliage peculiar to the Italian phase of the style, and gilded. The ceiling over the auditory takes the form of an extended fan from the arch spanning the prosceniun, and is divided into a series of geometric panels modelled in Renaissance ornament in relief, of the same character as the box fronts. Colour is sparingly used in the ceiling, the background of the ornament only being painted a pale yellow. The proscenium arch is divided by ribs into a series of panels, with gilded ornament. Over the proscenium, in the tympanum of the arch, is a *basso-relievo* of figures and ornament upon a gold ground. The walls of the auditory are hung with a rich embossed paper, in two tones of deep Venetian red. The seats are covered in peacock blue, plush being used for the stalls, and stamped velvet for the dress-circle. A gold-coloured satin curtain takes the place of the usual painted act-drop.

The stage, which is laid with all the latest improvements in mechanical contrivances, is 60 ft. wide by a depth from the float lights to the back wall of 52 ft.; there is a clear height above the stage of 56 ft. for the working of the scenery, and a sink below of 15 ft. Behind the stage, and occupying the whole wing of the building in Herbert's-passage, are the dressing-rooms and offices of the management.

The theatre is fitted with a complete system of gas-lighting, but this is only for use in case of emergency, the whole of the illumination for all parts of the establishment being by means of electricity; this has been undertaken by Messrs. Siemens & Co., and the lights adopted are those introduced by Swan, of Newcastle, and known as the "Swan Incandescent Light," the power necessary to generate the electric current for so many lights being supplied by powerful steam-engines placed in a separate building on the vacant land adjoining the theatre. These "Swan" lights are of a beautiful colour, and in no way impare the atmosphere of the theatre, and emit no heat; they are not of the piercing brightness of the electric light as seen in the streets and elsewhere, and, therefore, are not unpleasant to the eyes. This is the first instance of a public building being lighted permanently in all its departments by the electric light.

The exterior façade of the theatre is in Somerset-street, facing the Victoria Embankment, and both this and the Beaufort-buildings frontage are built of red brick, with Portland stone for all moulded parts, and are Italian in style.

The contractors who have been engaged upon the works are as follow:—

Patman & Fotheringham, for the whole of the builders' work, including the stage. Collinson & Lock have arranged the scheme of colour for the interior, and have executed the papering, painting, and gilding, and have supplied the upholstery and carpets; they have also modelled and executed the plaster ornamentation, in conjunction with Geo. Jackson & Sons. Strode & Co. have fitted up the gas arrangements. C. Wadman has manufactured the armchairs for the dress-circle and stalls. Burke & Co. have laid down the marble floor of the vestibule. C. Drake & Co. have executed the concrete floors and staircases. Faraday & Son have made the internal fittings in connexion with the electric lighting. Merryweather & Sons have supplied the fire-hydrants and other such appliances. Clark & Co. have constructed the revolving iron shutters and blinds at entrances.

Mr. J. E. Walker has been the architect's clerk of works.

The Town of Swansea has lately decided on filling the east window of St. Mary's Parish Church with stained glass, to commemorate the meeting of the Church Congress held there in 1879. The subject chosen is "Christ's Sermon on the Mount," and the execution of the work has been entrusted to Messrs. Mayer & Co., of New Bond-street.

PUBLIC WORKS AT IPSWICH.

IN addition to the public works lately described by us as having been carried out at Ipswich, we may usefully give some particulars of the new sewerage works, and of the new hospital for infectious diseases, both recently opened.

The Sewerage Works.—Ipswich has for many years been regarded as in an almost dangerous state, on account of a deficiency or absence of sewerage works. This was not only inconvenient, but the death-rate of the borough has, it is said, been higher than it should be, and considerably higher than it would be if proper drainage had been provided. This is a question upon which many years' consideration and discussion have been expended; and, indeed, it is just a quarter of a century since the Corporation began to talk of providing a sewerage system at Ipswich. Mr. Bruff was the first engineer consulted, and he drew up the very scheme which has now been adopted in substance, after consideration of a rival scheme for sending the refuse of the town on to a sewage farm on Nacton Heath. Part of Mr. Bruff's plan was to construct an intercepting sewer along the low-lying parts of the town to the river, at the Cliff Bight, and thence along the foreshore, past Hog Highland to the London Hard. Tenders were advertised for for the execution of the works, and Messrs. Pearson & Son, of Broomfield Works, Bradford, were the successful competitors. Messrs. Pearson at once set about the work, and in October, 1879, a commencement was made in the bed of the tail stream of the Gipping, at its commencement near Bird's Gardens. That tail stream (says the *Ipswich Journal*) had long been an abomination and an eyesore to the people of Ipswich; it conveyed a stream of filth and refuse to the Orwell, and was usually stigmatised as the open sewer, —a name which it well merited. The sewer here was 4 ft. by 4 ft., and far greater difficulties were met with in this part of the plan than had been expected. A thin deceptive crust had been formed, and it was found when the work was commenced there that the bottom was so rotten that much expenditure was needed for concrete, piles, &c., to fill up the great holes, in which were then only foul, oozy mud. Soon after the works had been commenced at this end, the outfall works were begun at the other extreme of the sewer, and here again the variable nature of the soil, and the depth of the ooze, greatly increased the difficulties beyond what had been expected, and the result was that it was not until some time after the rest of the sewer had been completed that the outfall works were ready for use. A portion of the site of the works had to be reclaimed from the foreshore of the river, and the depth of the ooze rendered this a work of considerable difficulty, as it absorbed large quantities of the earth which were thrown upon it to make the embankment. However, the embankment was completed in about six months, and the making of the sewer from that end was then proceeded with. No fewer than 400 men and 30 horses were employed upon the works, which made rapid progress, and the two ends of the sewer began to approach rapidly towards their point of union. The sewer is carried past the Greenwich Farm, along the foreshore, through the shipyards, past the Ship Launch Inn, and thence straight past the Gas Works. Thence it passes through St. John-street and Duke-street to the Fore Hamlet, into Fore-street, along which it was carried until it reaches Salthouse-street, and the works were then carried through into Key-street, past the Custom House, into College-street, across St. Peter's-street, into Grey Friars-road, and then through Mr. Cole's to the bed of the old Gipping tail stream, where it met that part of the sewer which had reached that spot from the upper end. The whole line of the sewer was thus completed last Christmas. The entire length is 2½ miles, and its size is increased towards the lower end from Lower Orwell-street, where it is 5 ft. by 5 ft., until it reaches the outfall works, at which point it is 11 ft. high. Almost the whole way along its route great difficulty has been caused, owing to the nature of the soil, much of it, even in the town, having been formerly subject to the influence of the tides, and it has been necessary to strongly shore up its side with timber for the safety of the houses on each side. The soil has generally been sand and gravel, and on the foreshore there has been ooze or slob to contend with. John-street was the only part of the work where the contractors had a continuity of strata of any length, but there there were still greater difficulties to be dealt with; and all through, the variable and bad quality of the soil, with frequent presence of water, threw great difficulties in the way of the undertaking. All the old sewers met with in the work were carried into the new sewer, and a temporary outfall was made near the Greenwich Farm to discharge the sewage while the outfall works were in progress. The outfall works were not completed until some time after the sewer, and the great difficulties which were met with there caused that work to be longer in hand than the rest. The outlet is 4 ft. above low-water mark; therefore, the water will have to stand and collect for a considerable part of the day in two reservoirs which have been constructed to receive it. The outlet to the river will be closed to keep out the tide, and five hours per day will be ample time for the discharge of the sewage of the town. The sewer will collect the refuse for the greater part of the day, and discharge it into the river when the tide is two-thirds ebb. The sewage first flows into a large brick chamber through a sluice-door or penstock, and round this chamber are various other penstocks leading to different parts of the works. Two of the penstocks will admit the sewage into the two large brick underground reservoirs. Each of these vaults is double-arched along its entire length (450 ft.), and each one is capable of holding 600,000 gallons. Here a great deal of the solid matter will settle, and the liquid will be poured from it to the river, but the best account to which to turn the sludge which will be left is a problem which as yet remains to be solved. Adjoining these covered reservoirs are two large tanks, each made chiefly of concrete, the larger of which will hold 1,000,000 gallons, and smaller 750,000. All rainfall will find its way to these works, and these two tanks are constructed solely for the purpose of providing for any extraordinary flow of water that may be thus caused. Messrs. Pearson & Son have fully carried out the provisions of their contract. Mr. H. Miller, jun., assistant to Mr. Bruff, superintended the progress of the whole work, and supplied all necessary lines, levels, &c. The contractors estimate that in the course of the works 130,000 cubic yards, or 200,000 tons, of earth, have been excavated. Over 6,000,000 of bricks were used, and of these 2,000,000 were made by the contractors at the outfall works from a vein of brick earth which was excavated there during the execution of the works, and which proved a most useful find to the contractors, who turned out 30,000 bricks per day. The rest of the bricks were brought by water from Yorkshire, at a cost of over 10 per cent. above those of ordinary local bricks. Three thousand tons of cement were used, and this was supplied by Messrs. J. R. Pattrick & Son, of Dovercourt.

The Infectious Diseases Hospital.—This building, opened on the 18th ult., is situated on a large piece of ground recessed some distance from the Foxhall-road, a short distance past the Borough Asylum. It has been erected by Mr. Richard S. Smith, of Northgate-street Works, from the designs of Mr. E. Buckham, the Borough Surveyor, in consultation with the medical officer of health, Mr. G. S. Elliston, and under the immediate supervision of Mr. C. Cullingham and Mr. N. Catchpole, two members of the Health Committee. Although the main consideration has been to provide buildings adapted for the treatment of patients in the most approved manner, the buildings have some architectural pretensions. They are in a style which may be described as a modest kind of Domestic Gothic, and consist of four blocks,—a central block and three blocks to the east, west, and north, connected with the central block by covered ways, open at the sides,—the three outer blocks being thus completely isolated from each other and from the central block, which is devoted to the administrative department. The buildings are of red brick, with Portland stone dressings. The administrative department includes rooms for the porter in charge and for other purposes; there being two sitting-rooms, kitchen and scullery, with store-room, larder, and other closets, including a wardrobe for the keeping of patients' clothing during the time they are in hospital. On the first floor are four spacious bedrooms, so that if a resident medical officer became necessary during an epidemic, rooms could be provided for him, or for night nurses if it became necessary to have a relay of nurses. The three covered ways radiate from the central building to the outer blocks. The complete

isolation of each block makes it possible to treat three kinds of infectious disease in the hospital at the same period. In each block two wards,—male and female,—are provided, each containing four beds. The nurses' room is between the wards, having a window affording a view of each, a stove at which minor cooking operations might be conducted, and a store-room in immediate proximity. At the end of each ward a door opens to a passage, with doors at each end of it to the open air, and with earth-closet, sink, &c. The interiors of the wards have a very cheerful appearance. They are well-lighted from windows on each side, and the walls are lined throughout with white glazed bricks, relieved by buff, brown, and blue bands, the glazed surface of the walls, which is impermeable to moisture, rendering it specially easy to wash them, and remove all traces of infection. The floors are of pitch pine, and the exposed timbers of the roofs, which are ceiled at the plate level, are also of pitch pine, stained and varnished. Considerable care has been taken also with regard to ventilation. Two fireplaces with brick chimneys occupy the centre of each ward, the stoves being Elsey's patent; and, in addition to upright ventilating tubes at the corner of each room, there are ventilating-shafts in connexion with each stove. These, communicating with outer air under the floor, bring in the fresh air, which, being carried through the flues at the back of the stove, is warmed before being discharged into the room. Beneath each bed there will also be movable ventilators for use if required, to admit fresh air. Foul air is intended to find its way out by ventilators in each chimney, immediately below the ceiling, and by a ventilator in the ceiling leading through a pipe to an Archimedian screw ventilator. The size of the wards gives 2,000 cubic feet of air space to each patient, with a floor space of 144 ft. to each, the ample floor and air space thus provided obviating the necessity for a convalescent ward. There being four beds in each ward, and six wards, accommodation is provided for twenty-four patients in all. The contract for the erection of the building was 3,649*l.*, and the extras are not serious. The hospital has the advantage of being built upon a dry subsoil of sand and gravel, and the drainage is disposed of by a system of subsoil-irrigation. It is collected at certain fixed points, and thence distributed by a system of land tile drains, at a depth of about 1 ft. 3 in. or 1 ft. 6 in. The discharge is facilitated by the used of Field's automatic flushing tanks. Besides the main buildings described, there are two detached buildings at the corners of the grounds. One of these contains, in two parts, the mortuary, and a chamber for infected linen. The other building is the laundry and coach-house.

A SEASIDE REFLECTION.

AN article in the *Builder* of August 13th, referring to the sanitary condition of many health resorts, seemed full of interest when lately read at one of our southern watering-places, and, illustrated as it was by present facts, its moral and warning were more full of importance than they otherwise might have been. No need for names when conditions are so similar. To interested parties the disparagement of one town is only a foil to exalt and show up the superexcellence of some equally unsanitary resort.

One would hardly feel disposed, during the few days or weeks of the annual holiday, to set himself the thankless task of instructing lodging-house keepers and local authorities in sanitary improvements, so that it seems probable that only by a slow and painful process will our older and smaller watering-places learn the necessity of setting their houses in order. Until then, the newer towns, where at least some regard has been had to hygiene, and those older towns that have boldly dealt with the question, will command increasing patronage and prosperity.

Three questions concern the health-seeking visitor:—First, the public sewerage and water-supply; secondly, the house system of drains and water and general construction; thirdly, the cleanliness and habits of the householders who "let lodgings." When the first and second are assured by competent local authority, the third will be pretty easily resolved by simple inspection. Until then the laborious and painstaking efforts of the most conscientiously clean "landlady" will be an unfair struggle against unknown evils.

As in surgical art, ready methods of treating cases are had recourse to when the elaborate appliances of an hospital are not at hand, so in sanitary matters much may be done at little cost to render a house fairly healthy. Ventilate the soil-pipe at its highest point; have an exit for foul air as high up as possible in every w.c., and so arranged that it cannot be shut; keep the door of the w.c. shut; let there be no direct connexion between the cistern or sink, and drain. Some of these may seem trifling, but, in reality, all are important.

Until there are many reforms inside and outside the houses where hang the cards bearing the tempting word "Apartments," sea-breezes and ozone, change of air and scene, will often be mysteriously negatived,—especially in the case of those most needing these advantages,—by the unwholesome lodging-houses where of necessity so many hours, even during the longest and brightest days of a summer's holiday, are spent.

ON THE PRESSURE OF WIND UPON A FIXED PLANE SURFACE.*

THE recent failures of the Tay Bridge and other important structures during heavy gales of wind, have attracted much attention to the subject of this paper. The general solution of this problem may be thus briefly stated:—

Let v = the velocity of the current in feet per second.

h = the height through which a heavy body must fall to produce the velocity v.

w = the weight in pounds of a cubic foot of the impinging fluid [for atmospheric air averaging about 0·0765 lb.]

g = 32, the co-efficient of gravity.

Then $h = \frac{v^2}{2g}$; and since p the pressure of a fluid striking a plane perpendicularly and then escaping at right angles to its original path, is that due to twice the height h [Daubuisson's Hydraulics; Rouse's Experiments] we have simply

$$p = \frac{wv^2}{g}$$

$$= \text{(for atmospheric air)} \frac{0\,0765v^2}{32}$$

$$= \left(\frac{v}{20}\right)^2 \text{very nearly.}$$

From this easily-remembered formula the following Table of Pressure is constructed:—

Velocities in		Pressures in
Feet per second.	Miles per hour.	lb. per square foot.
10	6·8	0·25
20	13·6	1·00
30	20·4	2·25
40	27·2	4·00
50	34·0	6·25
60	40·8	9·00
70	47·6	12·25
80	54·4	16·00
90	61·2	20·25
100	68·0	25·00
110	74·8	30·25
120	81·6	36·00
130	88·4	42·25
140	95·2	49·00
150	102·0	56·25

In general, only these, the maximum pressures, are required; but sometimes, as in the case of the inclined sail of a windmill or ship, or the roof of a building, the diminished pressure upon the surface placed obliquely to the *effective* current is needed; we have then

$$p = \left(\frac{v \sin \theta}{20}\right)^2$$

in which v = the absolute velocity with which the air strikes the receding plane; and θ = the internal angle made by the obliquely-placed surface, and the direction of the impinging wind.

With regard to the phenomenon called "a gust of wind," nothing is known, either as to its cause, or as to its exceptional but almost momentary velocity, or as to the extent of the area over which it temporarily operates; but it is, notwithstanding, certain that a wind pressure of even 40 lb. on the square foot is unknown in these islands, because, as may be readily shown, this intensity of pressure would have sufficed to overthrow most of the long-existing factory chimneys, to overset post windmills, and to scatter the greater number of the slighter built domestic and other structures which have, nevertheless, "weathered many a storm," and still remain intact.

It remains to make a passing allusion to whirlwinds, tornados, and waterspouts, all the results of spiral motions apparently produced in some obscure manner by electrical action. These phenomena are very rarely observed to occur on an important scale in these kingdoms. The powerful forces concerned in or generated by these erratic movements have never been measured, and, consequently, cannot be formulated; but it may be observed that were they known they could not be introduced with propriety into calculations of the strength of structures intended to have a commercial value, because of the extreme improbability of any particular structure falling within the range of their destructive effects. They are, in fact, within the legal category of "Actus Dei."

The conclusion of the author of this paper, therefore, is that for structural calculations a maximum wind pressure of 40 lb. per square foot may be very safely adopted, notwithstanding some reported anemometrical observations to the contrary.

With regard to these observations the author remarks that the instruments in use are little better than philosophical toys, and that, in general, they afford no direct, comparable, or reliable indications of either velocities or pressures; and that they are often so injudiciously placed as in some instances to record the effects of combined, and, therefore, locally accelerated currents; whilst, in other instances, they record only the effects of obstructed, and, therefore, locally retarded currents.

As the acquisition of accurate data is of great and increasing importance, the author suggests that the British Association and other learned societies interested in physical investigations should unite in providing the necessary funds and observers for the purpose.

* Revised by the author, Mr. Thomas Hawksley, F.R.S. Read at York.

THE LIVERPOOL UNIVERSITY COLLEGE AND THE CORPORATION.

THE Liverpool Corporation have just decided to obtain Parliamentary powers for purchasing lands and buildings in Brownlow Hill, adjoining the old lunatic asylum, which has been purchased by the Council of the new University College, and to reconstruct the buildings thus proposed to be purchased, for the purposes of the college (subject to the use of the portion not built upon as a recreation-ground), the amount to be expended being 30,000*l.* In moving that the Council apply for the necessary powers, the chairman of the finance and estate committee of the Council observed that the great necessity of the present day was to improve the higher education of the people, and that to give higher scientific education to the youth of the community would greatly benefit the city at large. It was not a question to be limited to "value received," for he believed the city would receive value a thousandfold from the college; and when they bore in mind that private citizens had contributed their thousands, he thought that the least the municipality could do was to contribute to the cost of the college. Some opposition having been made to the proposal, the mayor, in warmly supporting it, said that the great fault of the present day with regard to education was that a most magnificent education was provided for the children of the poor, while for the class which provided the greater part of the enterprise of the country in our manufactories, shipbuilding yards, mines, and the iron industries, absolutely nothing had been done. But the Liverpool College would not be entirely for the middle class; it would be open for those of the poorer class who showed intelligence, and they would receive grants from the Council of Education which would take them up to University College. The proposal was unanimously adopted.

The City of London College.—The present building in Leadenhall-street is too small for the work carried on, and it is proposed to erect a new building in White-street, Moorfields, at a cost of 15,000*l.*, towards which there is a sum of 5,000*l.* in hand. The council ask for assistance to carry this out, especially from the Corporation and large employers of labour in the City.

THE LIVERPOOL BUILDING AND SANITARY ACTS.

AMONGST the Private Bill applications to be made in the next session of Parliament is one by the Liverpool Corporation for powers to amend the local building and sanitary Acts, and it is intended to hold a conference with the Architectural Society on the several amendments which it is proposed to make in the existing Acts. Amongst others the contemplated amendments include powers to have cases of infectious disease compulsorily registered; also that powers shall be given to the Council to buy insanitary property by agreement, if they can, instead of compulsorily. They also propose to have control over the great network of telegraph wires over the town. During the discussion which took place when the proposed Bill was before the Council, Sir James A. Picton strongly supported its advisability, observing that its provisions were urgently needed in the interests of the city's welfare.

THE NEW EDDYSTONE LIGHTHOUSE.

THE lantern has been added to the new tower. The old lighthouse by its side looks singularly puny in contrast. All the exterior fittings are of gun-metal. The tower itself, as our readers are aware, is entirely of West country grey granite, save a few courses at the base, which are of Aberdeen. The lantern is the largest in the world. The fog-bells weigh each over two tons (4,486 lb. and 4,627 lb. respectively). They stand 4 ft. 6 in. high, and are 5 ft. 1½ in. diameter at the mouth. They are fixed 130 ft. above high-water mark. Messrs. Chance, of Birmingham, have put up the lantern. The bell-shaped cap above is 150 ft. above high-water mark. Plymouth may now boast of by far the finest light-house tower in the world. A very excellent photograph of it was taken last week by Mr. George Long, photographer, Union-street, Plymouth. The work is expected to be complete by the time of the proposed visit of the Associated Chambers of Commerce, which is fixed for October 6th.

DEVELOPMENT OF WATER POWER IN THE UNITED STATES.

AT the thirteenth annual convention of the American Society of Civil Engineers, held at Montreal lately, Mr. James Bicheno Francis, president, delivered an address, in the course of which he said:—Water-power in many of the States is abundant, and contributes largely to their prosperity. Its proper development calls for the services of the civil engineer, and as it is the branch of the profession with which I am most familiar, I propose to offer a few remarks on the subject. The earliest applications were to grist and saw mills; carding and fulling mills soon followed; these were essential to the comfort of the early settlers, who relied on home industries for shelter, food, and clothing, but with the progress of the country came other requirements. The earliest application of water-power to general manufacturing purposes appears to have been at Paterson, New Jersey, where "The Society for Establishing Useful Manufactures" was formed in the year 1791. The Passaic River at this point furnishes, when at a minimum, about eleven hundred horse-power, continuously night and day.

The water-power at Lowell, Massachusetts, was begun to be improved for general manufacturing purposes in 1822. The Merrimack River at this point has a fall of 35 ft., and furnishes, at a minimum, about ten thousand horse-power during the usual working-hours.

At Cohoes, in the State of New York, the Mohawk River has a fall of about 105 ft., which was brought into use, systematically, very soon after that at Lowell, and could furnish about fourteen thousand horse-power during the usual working hours, but the works are so arranged that part of the power is not available at present.

At Manchester, New Hampshire, the present works were commenced in 1835. The Merrimack River at this point has a fall of about 52 ft., and furnishes, at a minimum, about ten thousand horse-power, during the usual working-hours.

At Lawrence, Massachusetts, the Essex Company built a dam across the Merrimack River, commencing in 1845, and making a fall of about 28 ft., and a minimum power, during the usual working-hours, of about ten thousand horse-power.

At Holyoke, Massachusetts, the Hadley Falls Company commenced their works about 1845, for developing the power of the Connecticut River at that point, where there is a fall of about 50 ft., and at a minimum, about seventeen thousand horse-power during the usual working hours.

At Lewiston, Maine, the fall in the Androscoggin River is about 50 ft.; its systematic development was commenced about 1845, and with the improvement of the large natural reservoirs at the head waters of the river, now in progress, it is expected that a minimum power, during the usual working-hours, of about eleven thousand horse-power will be obtained.

At Birmingham, Connecticut, the Ousatonic Water Company have developed the water-power of the Housatonic River by a dam giving 22 ft. fall, furnishing, at a minimum, about two thousand horse-power, during the usual working hours.

The Dundee Water and Land Company, about 1858, developed the power of the Passaic River, at Passaic, New Jersey, where there is a fall of about 22 ft., giving a minimum power, during the usual working-hours, of about nine hundred horse-power.

The Turner's Falls Company, in 1866, commenced the development of the power of the Connecticut River at Turner's Falls, Massachusetts, by building a dam on the Middle Fall, which is about 35 ft., and furnishes a minimum power, during the usual working-hours, of about ten thousand horse-power.

I have named the above water-powers as being developed in a systematic manner from their inception, and of which I have been able to obtain some data. In the usual process of developing a large water-power, a company is formed who acquire the title to the property, embracing the land necessary for the site of the town to accommodate the population which is sure to gather around an improved water-power. The dam and canals or races are constructed, and mill sites with accompanying rights to the use of the water are granted, usually by perpetual leases, subject to annual rents. This method of developing water-power is distinctly an American idea, and the only instance where it has been attempted abroad, that I know of, is at Bellegarde, in France, where there is a fall in the Rhone of about 33 ft. Within the last few years works have been constructed for its development, furnishing a large amount of power, but from the great outlay incurred in acquiring the titles to the property, and other difficulties, it has not been a financial success. The water-powers I have named are but a small fraction of the whole amount existing in the United States and the adjoining Dominion of Canada. There is Niagara, with its two or three millions of horse-power; the St. Lawrence, with its succession of falls from Lake Ontario to Montreal; the Falls of St. Anthony, at Minneapolis, and many other falls, with large volumes of water, on the upper Mississippi and its branches. It would be a long story to name even the large water-powers, and the smaller ones are almost innumerable. In the State of Maine a survey of the water-power has recently been made, the result, as stated in the official report, being "between one and two millions of horse-power," part of which will probably not be available. There is an elevated region in the northern part of the South Atlantic States exceeding in area one hundred thousand square miles, in which there is a vast amount of water-power, and being near the cotton fields, with a fine climate, free from malaria, its only needs are railways, capital, and population to become a great manufacturing section. The design and construction of the works for developing a large water-power, together with the necessary arrangements for utilising it, and providing for its subdivision among the parties entitled to it, according to their respective rights, affords an extensive field for civil engineers, and, in view of the vast amount of it yet undeveloped, but which with the increase of population and the constantly increasing demand for mechanical power, as a substitute for hand labour, must come into use, the field must continue to enlarge for a long time to come. There are many cases in which the power of a waterfall can be made available by means of compressed air, more conveniently than by the ordinary motors. The fall may be too small to be utilised by the ordinary motors; the site where the power is wanted may be too distant from the waterfall, or it may be desired to distribute the power in small amounts at distant points. A method o compressing air by means of a fall of water has been devised by Mr. Joseph P. Frizell, C.E., of St. Paul, Minnesota, which, from the extreme simplicity of the apparatus, promises to find useful applications.* The principle on which it operates is by carrying the air in small bubbles in a current of water down a vertical shaft to the depth giving the desired compression, then through a horizontal passage, in which the bubbles rise into a reservoir near the top of this passage, the water passing on and rising in another vertical or inclined passage at the top of which it is discharged, of course at a lower level than it entered the first shaft. The formation at waterfalls is usually rock, which would enable the passages and the reservoir for collecting the compressed air to be formed by simple excavations with no other apparatus than that required to charge the descending column of water with the bubbles of air, which can be done by throwing the water into violent commotion at its entrance, and a pipe and a valve for the delivery of the air from the reservoir. The transfer of power by electricity is one of the problems now engaging the attention of electricians, and it is now done in Europe in a small way. Sir William Thomson stated in evidence before an English Parliamentary committee, two years ago, that he looked "forward to the Falls of Niagara being extensively used for the production of light and mechanical power over a large area of North America," and that a copper wire half an inch in diameter would transmit twenty-one thousand horse-power from Niagara to Montreal, Boston, New York, or Philadelphia. His statements appear to have been based on theoretical considerations, but there is no longer any doubt as to the possibility of transferring power in this manner; its practicability for industrial purposes must be determined by trial. Dr. Paget Higgs, a distinguished English electrician, is now experimenting on it in the city of New York.

CONSTRUCTION OF PUBLIC LIBRARIES.

AT the final meeting of the Library Association, held last week in the Hall of Gray's Inn, Mr. William Archer, librarian of the National Library of Ireland, read a paper entitled "Suggestions as to Public Library Buildings: their Internal Plan and Construction, &c.," in view of the intended transference of the books constituting the National Library of Ireland to another building. Briefly, the requirements were stated as "compact stowage to save space, combined with short distances to save time." There should be a good-sized, lofty and commodious, well-heated, well-lighted, well-ventilated, comfortably-fitted, and tasteful reading-room for the general public, and side by side two or three minor rooms for more exclusive study, one of which should be devoted to lady readers. It was desirable also to have a small room for conversation. In these rooms no book should be kept except books of reference, which the public might take from the shelves. The books should be brought from the stores by attendants, and the rooms might be classified, being devoted to different classes of readers, such as the readers of light fiction and those reading more recondite subjects. The stores of books, or library proper, should be in the apartments adjoining, and, as much as possible, grouped around the reading-rooms. They should be approached without necessarily intruding upon or passing through the reading-room. The reader of the paper dwelt at length on the nature of the internal fittings of the store-rooms, and recommended that the reading-room should be on the first story of the building, so that the ground-floor and the second floor might be available for storage. Obviously a library building ought to be isolated, and it should, as far as possible, be fireproof. To aid in the latter purpose the bookcases and tables might be made of iron, covered with leather to obviate injury to the books. The structure of the building should be so planned as to admit of future extension of storage room. Such an arrangement as he had suggested would meet the requirements of a library for a much longer period than the methods now in vogue. What was wanted was despatch in bringing the books required from the shelves and placing them at once before the readers; and the advantages of this plan he thought would be obvious. Distance and effort

* Journal of the Franklin Institute for September, 1877.

would be reduced to a minimum, and time would be manifestly saved. The paper concluded by a reference to a plan for library buildings suggested by Mr. W. F. Poole, librarian of the City Public Library, Chicago, and some points of difference were noticed. Mr. Archer stated that the general ideas and leading principles of his plan, as submitted to the council of trustees of the National Library, had been approved, and he expressed a hope that they might be embodied in the plans which the architect might be called upon to make.

ELECTRICITY AS A MOTIVE POWER.

AT the Electrical Exhibition in Paris, various machines show the application of machinery as a motive power. For example, there is a circular saw driven by electricity. The diameter of the saw is 3 ft., and the planks upon which it works are 5 in. thick. M. Piat exhibits in the same part of the building a stone cutter and an electrical hammer, which does all the work usually assigned to a steam hammer. Close to these machines is another for pumping water, driven by a Gramme motor; the large volume of water which is thrown out conveys to the eye some idea of the great force which can be transmitted by electricity, although, in reality, this machine does not require nearly so much force as many other motors in the exhibition. In the same corner we find a number of machines for driving band-saws, and so forth, all driven by the convenient little motor of M. Deprez. Near to this spot there is also a rock-drilling machine. The drill rotates under the influence of a Gramme machine, and while a hole is being bored it advances under the influence of the water pressure obtainable in Paris, which is about three atmospheres.

RAILWAY COTTAGE BUILDING.

AT the recent half-yearly meeting of the North Eastern Railway Company, the chairman made some interesting observations in reference to the building of cottages for the servants in the company's employ, from which it appears that this particular class of dwellings have been erected on an extensive scale by the North Eastern directors. He said that at different times the company had taken power to build cottages for the accommodation of those in their employ; and they had now no fewer than 2,324 cottages, each of which had its own garden attached. The rent paid was a fair interest on the money laid out, and the cottages were built in places where the servants of the company could not otherwise obtain house accommodation. The company had in this way laid out nearly half a million. In addition to the cottages with gardens he had mentioned, there were 1,000 more cottages which had no garden attached to the house, but in the great majority of cases they had patches of land, sometimes on the side of the line, and sometimes at a little distance. The company had in this respect been making what he regarded as a very wise and judicious investment for themselves, besides adding materially to the comfort of their servants.

MACHINE-MADE LACE.

IN the first Cantor Lecture on the art of lace-making, now in course of publication, Mr. Alan S. Cole says:—Our English pillow-lace workers adopted some of the Brussels patterns and some of the Mechlin; but English taste was easily gratified by less skilfully arranged patterns, and found sufficient pleasure in the peasant laces of Buckinghamshire and Devonshire. It is these patterns that a good deal of the machine-made lace imitates, though within the last three or four years there has been a marked phase of other more ambitious imitation in the machine-lace trade. Something akin to the rich patterns of ancient hand-made lace is new made by the machine, and to the majority this substitution of machine-made for hand-made goods is satisfactory. As a rule, the difference between machine and hand made lace is not detected by the many. If there is a difference, to some it is that machine-made lace, from some points of view, is the more wonderful and more to be prized of the two sorts of work. Setting aside any prejudices one may have, and reviewing the variety of forms wrought years ago, we may consider some of the circumstances of the production of laces. Sometimes laces were made in dim and dark cellars, so that the soft fragile threads should retain their elasticity, and not become brittle. A ray of light alone was allowed to fall upon the workwoman's cushion. What an expense of eyesight and health must then have taken place! Compare truly costly works produced in such circumstances, with the low-priced repetitions done in taut wiry cotton threads which grow with precise monotony of pattern in the bustle and clatter of machinery, at the expense of iron and steam, and one is perhaps inclined to be glad at the release of human labour from penalties like those which formerly accompanied lace-making. I do not think any one can well say what may succeed to the mechanically devised and produced materials now called lace. They seem to satisfy present demand and to reflect the taste and ability of the age. Is it vain to hope for a revival of hand-made works? Is the time to arrive when machinery shall have exhausted itself in its endeavours to infuse into its productions the quality of handwork, or has a period commenced when people shall be contented with mechanical instead of manual art, and so from this, possibly, pass on to a condition of indifference to fine artistic works of handicraft, which not many years since were reported to have been pronounced by a philosopher and leader of opinion to be but the rubbish of human labour?

PATENT RECORD.*

ABRIDGMENTS OF SPECIFICATIONS

Published during the Week ending Sept. 3, 1881.

5,509. J. H. Corke, Southsea. Material for making chimneypieces, &c.

This is composed of 6 lb. of sulphate of iron, 4 lb. sulphate of aluminia, and 3½ lb. logwood, placed in 18 gallons of water, and boiled for two hours. The mixture is then strained and cooled. It is then run into moulds, and thoroughly dried by heat, when it is ready for use. Dec. 31, 1880. Price 2d.

247. F. Winterhoff and H. C. Webb, Worcester. Ornamental enamelling of iron, glass, &c.

The surface to be ornamented has a coating of enamel. The outline of the design is drawn on a stone, and an impression taken on transfer paper. The outline on paper is then transferred by pressure on the enamelled surface, and is burned into it. Colour is produced by printing on the paper in adhesive enamel colour, and transferring it to the surface. The pressure is effected by a pair of rollers, the lower one of wood, the upper of india-rubber. Jan. 20, 1881. Price 6d.

313. H. Skerrett, Sparkbrook. Apparatus for opening, closing, and fastening certain kinds of windows and skylights.

This is applicable to those windows, &c., that are hung or centered on pivots. A quadrant bar is fixed to the top of the window frame, and on the upper part of the sash is a plate, through which the quadrant bar passes. On the top of this plate is a cranked lever, the short arm of which takes into notches on the upper edge of the quadrant. A spring is fixed on the long arm to keep the short arm in these notches. A cord is fastened to the long arm to lift the short arm out of the notches, and to open the window. The other end of the cord passes over a pulley, and is fastened to the sash to close it again. Jan. 24, 1881. Price 8d.

351. R. Jackson, Leeds. Warming and heating buildings, tanks, vehicles, &c.

A lamp is enclosed in a pipe with a bell-shaped mouth, which pipe is continued in coils to heat the building, &c. (*Pro. Pro.*) Jan. 26, 1881. Price 2d.

387. J. Britton, Stamford. Firegrates or containers.

The object of this is to obtain "slow combustion" in common grates and stoves. A form is made of fireclay to fit the grate with bottom, back, and two sides. This is placed in the grate. Jan. 28, 1881. Price 6d.

392. T. J. Sloan, St. Maude, France. Apparatus for thawing ice in water supply-pipes, &c.

A portable boiler is used, the steam in which forces the hot water up in a flexible tube, which is inserted in the pipe to be thawed and forced into the same by springs. (*Pro. Pro.*) Jan. 28, 1881. Price 2d.

403. T. Bate, Kilburn. Ventilating pots or cowls for soil-pipes.

The cowl is the ordinary cone chimney-cowl, but at the top of the cone is an outlet, from which rises a cylinder of wire gauze, above which is a cap. The wire gauze prevents any down-draught. Jan. 29, 1881. Price 4d.

406. J. Hopkinson, Manchester. Apparatus to prevent the formation of ice in water supply-pipes.

A copper ball or chamber is connected with the main supply pipe, as near its entrance into the building as possible. This is inclosed in a cover or hood of fireclay, with a hole in the top, which rests on a perforated plate. Through this passes the gas-burner, and when this is lighted the water in the ball is heated and rises in the supply-pipe. Jan. 29, 1881. Price 6d.

410. L. J. Newman, Inchbrook. Cistern valve.

A tubular valve is used, from the upper end of which passes a tube which reaches to the water level, and which therefore serves as an overflow pipe and as an air-pipe to the valve. (*Pro. Pro.*) Jan. 31, 1881. Price 2d.

Published during the Week ending Sept. 10, 1881.

380. W. Leggott, Bradford. Closing and fastening doors.

In the bottom of the hanging style of the door is the centre of a toothed pinion, which works into a rack placed in guides. At the end of the rack is a screwed spindle, round which is coiled a spring. When the door is opened the pinion actuates the rack and puts the spring in tension, which shuts the door again, when it is liberated. A bolt is arranged to lock the rack and fasten the door. Jan. 28, 1881. Price 6d.

439. E. J. Hill, Westminster. Means of hanging or supporting window-sashes and blinds, &c.

A rod is fixed vertically to the frame. A piece of metal, with a hole in one extremity to work over the rod, is placed loosely in a frame, which is fixed to the sash. This piece of metal works on a fixed fulcrum, and while the hole is in line with the rod, the sash will move freely, but when it is turned the eye grips the rod and prevents the sash moving. (*Pro. Pro.*) Feb. 2, 1881. Price 2d.

523. J. Westley, Birmingham. Fire-places.

The back is formed of fire-clay, &c., with a nearly horizontal projecting part above the fuel to radiate the heat into the room. (*Pro. Pro.*) Feb. 7, 1881. Price 2d.

536. R. H. Gudgeon, Winchester. Chimney-piece coverings or castings.

The jambs and friezes of the chimney-piece coverings are made in separate parts, and so fixed that they can slide one on the other as required. They can, therefore, easily be adapted to any different size or form of chimney-piece. Feb. 8, 1881. Price 6d.

CHURCH DECORATION.

New Mills (Derbyshire).—St. James's Church, erected a very few years since at the cost of Mr. and Mrs. John Mackie, of New Mills and Wakefield, as a memorial to the lady's parents, has been re-opened for service after receiving interior art decoration. This is subordinated to the architectural features of the building, which it emphasises. The more novel detail is the introduction within four pointed arch wall-recesses in the nave of as many groups of spirit-fresco painted figures, embracing the subjects of Christ blessing Little Children, the Sermon on the Mount, Feeding the Five Thousand, and the Final Commission to the Apostles, with suitable text legends beneath. These groups compose pyramidally, and are in dark outline, relieved by a dull Indian red background, with here and there a little gold. In the ornamented bases are emblems of the four Evangelists. The artists of the frescoes and decorations are Messrs. Powell, Brothers, of Leeds,—Mr. W. Swinden Barber, of Halifax, being the supervising architect.

LONDON FRONT GARDENS.

PASSING through the familiar districts of South Kensington and Earls Court the other day, among many large and many well-built houses, one general drawback was very evident. It was the want of front gardens, which, in a neighbourhood comparatively suburban, is a great fault. We are perfectly aware that the high value of land around London makes it difficult to devote even a small portion as a garden to each house, but in many cases it is quite practicable to do so; that is, just sufficient to operate as a screen and as a pleasant and refreshing relief to the buildings.

In going up one road and down another, among tall houses without any vegetation visible, it is wearisome to the eye to see nothing but bricks, mortar, and dust,—dust, mortar, and bricks, whichever way we turn. It reminds us of the agreeable nickname of "The Catacombs," bestowed by Thackeray on the Harley-street region. There is now, of course, no remedy for streets which are already built over, but in future we wish to invite the attention of owners, architects, and builders to the vast improvement which is given to the appearance of a street by having a limited patch of green before each house. Much ground could not be afforded, and again, ladies, as a rule, do not like long front gardens in which during rain a bonnet may be spoiled while passing from the carriage or cab to the door. But a slip, even two or three yards wide, irrespective of the area, would hold some evergreens or a small tree, and give the agreeable relief which we advocate. As an instance in question, we may point out the district of Campden-hill, where the houses are set back a total distance, including areas, of from 10 ft. to 15 ft., the front space planted with evergreens; this is a pleasant and successful part, including Phillimore-gardens, Essex and Durham villas, Stafford-terrace, &c. Leinster-gardens,

Bayswater, is another instance. Parts of Cromwell-road, Queen's-gate, Harrington-gardens, and other streets farther out, are examples, on the contrary, of the dry and unrelieved style.

H. & R. POWELL.

LINCOLN'S INN CHAPEL.

THE Chapel of Lincoln's Inn is a work by Inigo Jones,—a dated work, too, for it was consecrated on Ascension Day, 1623,—and is an example of the latest phase of Gothic architecture. Without asserting that the old is in no case to give place to the new, we may surely, in this case, seriously ask under whose advice, and for what justifying purpose, have parts of this interesting building been demolished, and whether or not more is to follow? The well-known groined staircase has been knocked down, and the "pieces" are deposited in the groined open way beneath the chapel, where lawyers were wont to walk "and confer their learnings." One of the masons engaged in the work was somewhat indignant when we termed this "destruction," and asserted that all the pieces were numbered, and that he intended to make a drawing so that the staircase might be put back again twenty years hence if desired! We endeavoured to learn who was the architect who took the responsibility of this regrettable act, but failed,—none of the workmen about knew anything of him. It is sincerely to be hoped, this matter having already been publicly commented on, that proper pressure has been brought to bear on the Benchers.

VERGERS AND CATHEDRALS.

SIR,—I have the pleasure to inform "C. T. H." that at the meeting of the British Association the members were saved the infliction of the verger. Those who visited the Minster did so under the guidance of the Dean or one of the Canons. I was one of a large party conducted by the Dean. He was instructive and cheerful, without being vulgar, and he did not offer to lay a wager with any of us upon the extent of our ignorance.

The suggestions contained in the last paragraph of the letter of "C. T. H." are admirable, and will, I hope, be carried out.

The remarks of Mr. Smirke do not touch the point at issue at all. He could not have gone over the cathedral with the mob at 6d. a head, or he would not have been allowed to spend an hour in the crypt making notes for his pattern-book. He must have had a special privilege granted to him, which, doubtless, entailed "a complex and delicate" tip to "the model of politeness and intelligence." Grammatical exactitude and propriety of expression are, perhaps, not necessary for intelligence; or there may be a superior verger kept for architects and private visitors. Should this not be the case, and Mr. Smirke intends publishing his notes of the information acquired from the verger, I hope he will submit them beforehand to some friend familiar with the acquirements of grammatical propriety, so that the solecisms may be corrected. Being allowed to see the cathedral under exceptional circumstances, how can he venture to give an opinion of what is said to "the large number of persons of different capacities" by the verger whose vulgar nonsense I quoted?

Mr. Smirke, excusing the vergers of England by what is done at St. Denis, convinces me that he must have been at the same school with that eccentric logician who made so strange a reply when he was told how dirty his hands were.

F. S. A.

SIR,—There is, at least, one cathedral in England where one may revel amidst glorious chapels, and amongst wondrously beautiful detail, without having a verger at one's coat-tails, and that is at Exeter. The duly appointed officials are always in attendance, but the merest hint that one prefers to stroll quietly about by one's self is at once sufficient for Messrs. Parsons and Thomas, the vergers in question, who are always perfectly content to leave the visitor to follow his own courses until the next service hour. The only restriction put upon the public, and that a most vexatious one, is that no permission can be given to sketch without going through a formula which might possibly take several days to comply with. What with getting the Dean's permission, to allow the Canon in residence, to instruct the Cathedral surveyor, to direct the clerk of works, to give the vergers orders, to permit you to draw and the running about from pillar to post that all this involves, the short hours during which the sacred fane is available to the public so soon slip away that, as a rule, people find the procuring of the necessary permit very much more bother than it is worth.

Yet, be it remembered, Exeter Cathedral boasts of two of the finest Norman towers in England (built 1107—1206). The most perfect and beautiful Early English oak carvings in this country are Bishop Bruere's (1224–44) half-hundred choir-seats; and certainly the loveliest wood-carvings belonging to the Decorated period are to be found upon Bishop Stapeldon's exquisite throne, which is itself by far the largest and most magnificent bishop's throne in the entire world. Again, the sedilia, made in the same bishop's time, and wrought entirely of stone from the neighbouring quarry of Beer, is probably one of the lightest and most delicately-exquisite specimens of Decorated masonry in existence. Further, the most imposing and majestic feature in the whole building is the unbroken run of Exeter Cathedral's roof groining. It is nearly 400 ft. long, and gives a continuous succession of gracefully-vaulted lines, which are not exceeded in beauty by any roof I ever saw in my life,—"There is a skeleton in every house," the old saw says; and the one that exists at Exeter is the unnecessary difficulties placed in the way of drawing. Between service hours every visitor should have a perfect right to make such notes and sketches as suggest themselves. Englishmen are apt to kick against asking the permission of that old fogey and of this, to do that which the natural instinct of every properly-reasoning man tells him he has an absolute right to do.

HARRY HEMS.

SIR,—On more carefully reading the letters on the above, I find I was mistaken as to the character of the complaints from "F.S.A." and others. I thought myself justified in making the remarks I did, as, after a long absence, I have spent much time in visiting our cathedrals. Of course, I quite agree with your correspondents that vergers are "bores," and that their company is unfairly forced upon visitors. They should, in fact, only act as policemen and custodians of the noble buildings to which they are attached. If, by your powerful influence, you can bring about such a happy state of things, and make a visit to our sacred buildings less like "doing" the State Apartments at Windsor or the Tower of London, you will, I am sure, earn the lasting thankfulness of all.

SYDNEY SMIRKE.

THE CHURCHES AND TOWNS OF BUCKINGHAMSHIRE.

SIR,—Permit me to correct an error under which, as I think, the writer of the article on "Maids Morton Church," in your last issue, evidently labours. He says:—

"Buckinghamshire is by no means a rich county for the ecclesiologist, and it is somewhat singular that in such a purely agricultural district the towns should be so remarkably uninteresting, and the churches should have fared so badly. Yet, somehow or other, the important towns in Buckinghamshire seem to have been deprived of their ancient churches about a century or so back, and for what reason it is impossible to say."

And not content with running down our churches, he proceeds to speak very disparagingly of our towns. Now, in both these respects he is wrong. Does he know Newport Pagnell? Here is a town, although with a population some hundreds less than 4,000, yet with a church which, for size, beauty (both of external situation and internal arrangements), and attendance is not to be surpassed in this or any other county; and a town which, for its High-street, and the shops in it, excels many in other counties with double and treble its population. And the same might be said of many other towns and churches in Buckinghamshire.

I trust to your sense of justice to insert these few lines with a view of counteracting an erroneous impression which may have been produced respecting our county by the article in your last issue already referred to.

JOSEPH SIMPSON.

P.S.—Newport Pagnell Church (both external and internal) and the High-street, would make excellent illustrations for the pages of the *Builder*.

Glass-covered Iron-ware.—Is this manufacture still carried on? More than one correspondent asks us the question.

FIRE AND WATER.

SIR,—I, like many others, seek your aid when in distress, and will thank you to insert my remarks in your next issue on the subject to which they apply, namely, that of the defective provision for extinguishing fires in the metropolis. This subject you have handled over and over again, and I fear I cannot use terms sufficiently strong to induce you to place them before the public. Let the subject speak for itself, and direct your decision, viz., the security of lives and property, and the reduction of destruction thereof; and wherein myself and many readers of your journal see no difficulty. I remember some few years ago reading a proposition made by a gentleman of some standing in the metropolis, and evidently with some knowledge of the subject, being before the Common Council or the Metropolitan Board, a scheme for providing elevated reservoirs in certain parts of the City, whereby mains, and thus hydrants, would be constantly supplied or charged; so that at the outbreak of a fire a policeman on that beat could connect hose, which would be enclosed in the nearest recess available, same as now done in the Pavilion at Brighton, and elsewhere, and be able to connect to the nearest hydrant and turn on without waiting for fire-engine or any other aid. That proposal was not accepted, and thus the heart of London is left unprotected. I, as a practical man, consider that was a scheme, if I may use the term, which would, had it been carried out, have saved many lives and much property. The late fire in the City exemplifies the necessity of some such ready application, and until such provision be made lives and property will be at stake.

It is a disgrace to the metropolis, or to the managers or mismanagers, that London should be last in the race of water supply for the inhabitants and provision for extinguishing fires. The talent that can be brought to bear on this important question is within call. Many engineers, and thoroughly practical, would soon devise the machinery and arrangements, and give a guarantee for its efficiency to accomplish this end. The pecuniary matter should be a secondary consideration. Taking all in all, and our noble Prince lending his presence and assistance to attain the desired end, I do consider it reflects strongly on those in office and power, when all interested can look around in the provinces and see the wise provision made for the security and prosperity of its inhabitants.

Pray, Mr. Editor, do all you can to bring this important subject forward. Urge on, as you have already done, the necessity, and show forth the grave and responsible position of those who are in power, and neglect to bring about the remedy so easily attainable.

T. S.

OWNERSHIP OF BILLS OF QUANTITIES

SIR,—Will one of your numerous readers, who is an architect or quantity surveyor, kindly inform me (in the following case) as to the ownership of a priced and moneyed-out set of lithographed bills of quantities upon which a builder had *successfully* tendered? Do they belong to the builder or the architect, who had taken off his own quantities? The builder, although successful, had to submit to a revised estimate being prepared by the architect, the whole of the works coming to too much money, and these quantities were borrowed to form the basis of the valuation of the revised estimate. I was then called upon to represent the builder, and the revised estimate not being to my satisfaction, I withdrew the builder's original tender. The architect then claimed and refused to give up the lithographed priced and moneyed-out bills of quantities, upon the ground that they had not been paid for, and, consequently, were his property. Certainly the charges for lithography had not been paid, neither had the charges for taking off the quantities; nevertheless, under these circumstances, did these bills of quantities belong to the architect or the contractor?

WILLIAM H. PIPE.

SCHOOL-BOARD SCHOOLS.

Peckham.—The new Board-school in Wood's-road, Peckham, has been opened by the School Board for London. The school, which is the 239th new building opened by the Board, and the 60th in the Lambeth division, is built to accommodate 1,400 children. The cost of the building has been 8*l.* 16*s.* 6*d.* per child, and the cost of the site has been somewhat under 6*l.* per child. The school has been erected from the designs of Mr. E. R. Robson, the architect to the Board.

Salford.—On the 17th inst., Mr. Joseph Rice, the vice-chairman of the Salford School Board, laid the memorial stone of the Trafford-road Board-school, now being erected in the Ordsal ward to provide accommodation for 600 children. The school is situate at the corner of West Worsley-street and Robert Hall-street. The main building in Robert Hall-street is two stories high. On the ground-floor is to be the girls' department, which will have a schoolroom 50 ft. by 32 ft., and two class-rooms, 17 ft. by 16 ft. The entrance will be in London-street, and adjoining the entrance a cloak-room will be provided. The boys' department, on the upper floor, will have similar accommodation to the girls', and be entered from West Worsley-street by a well-lighted staircase. The infants' department is to be at the rear of the main building, and only one story high; it will include a main schoolroom and a large class-room for the junior infants. Large playgrounds are to be provided, of which a considerable portion will be covered. The buildings will be in the Gothic style. The fronts are being faced with selected brick. The string-courses and other dressings are generally in red terra-cotta. The contract for the whole of the work, amounting to 4,750*l.*, is being carried out by Mr. J. L.

Ward, builder, Manchester, from the designs and under the superintendence of Mr. Henry Lord, architect, Manchester.

Miscellanea.

Middle-Class Education.—A new middle-class school for 200 girls was opened last week in Chenies-street, Tottenham-court-road, the whole cost of which, amounting to several thousands of pounds, has been defrayed by a lady of the Goldsmid family. The school site happens to be on the edge of the Bedford Estate, adjoining the land which, centuries ago, was bequeathed for educational purposes by John Carpenter to the City of London, and which gave rise to the present City of London School. The new school and its playground occupy a corner site, about 70 ft. square, of which about one-half is built upon, the remainder being an open playground. The building is, inclusive of the basement, five stories high. The teaching department is entirely on the ground and first floors, and consists of five class-rooms, each holding forty children. As it is occasionally desirable to have a room or hall large enough to accommodate all the pupils, for lectures, examinations, prize distributions, or similar occasions, and the site is insufficient for the construction of a separate room for such purposes, three adjoining class-rooms on the first-floor have been so constructed with movable partitions that they can be thrown together, thus forming a single compartment, about 66 ft. by 22 ft. By these shifting partitions the entire clear length and width of the three class-rooms are obtained for the formation of the hall, without the obstruction usually caused by movable partitions. Each separating partition consists of three widths, the two side-widths being large doors, folding back against the walls, the central width being a thick sound-proof revolving wood shutter, sliding up and down in grooves on the edges of the closed doors. On the first-floor there are three sound-proof music practising-rooms, with double doors; and on the basement, level with the playground, are luncheon-rooms for pupils and teachers, cloak-room, lavatories, &c., and kitchen and living-rooms for the caretaker. The second floor is devoted to the head-mistress; and the third floor, in the roof, forms a large winter or wet-day playground, which will be fitted with suitable gymnastic apparatus. The exterior of the building, which is faced with red bricks and red Mansfield stone dressings, is an adaptation of the Early French Renaissance style, the high-pitched slated roof containing the second and third floor stories. The architects are Messrs. Davis & Emanuel.

Scroll Ornamentation.—At a recent meeting of the Royal Historical and Archæological Institute of Ireland, Mr. Marcus Ward exhibited a rubbing and coloured tracing of Hiberno-Romanesque scroll ornamentation from the old church of Maghera, county Londonderry, and contrasted therewith the engraving of the same scroll work given by Lord Dunraven in his work on "Irish Ecclesiastical Remains," showing the inaccuracy of the latter. He drew the attention of the meeting to the wealth of artistic design which the work displayed, exemplifying the varied fancy of the early artists of Ireland. Mr. Wakeman objected to the idea that the famous Opus Hibernacum, for which Ireland was celebrated during the Middle Ages, was derived from foreign sources, and he pointed out that on the oldest megalithic monuments of Ireland, the elements of all classes of ornamentation, such as are found in the earliest manuscripts of the country, and even upon churches of a comparatively late period, can be traced.

The Fish Market Accommodation in London.—This subject is now, as readers of the daily papers know, occupying the attention of the Special Committee of the Corporation of the City of London, and instructions have been given that any suggestion as to a site for such market forwarded to the City Architect, Guildhall, on or before the 28th instant, will be considered.

An Exhibition of Domestic and Sanitary Appliances was opened at Wolverhampton on Monday last. Gas and other stoves are largely represented, Messrs. Barnard, Bishop, & Barnard, and other well-known firms, being exhibitors.

The Brighton Exhibition.—The eighth annual exhibition of modern pictures in the Pavilion at Brighton is now open. The private view took place on Wednesday, the 21st.

"Not an Arch; Something in Architecture."—Mr. F. T. Dollman, in his recent work on the Church of St. Mary Overie, Southwark (now commonly known as St. Saviour's), refers, if we mistake not, to the unseemly contests that have occurred from time to time in connexion with the election of "Chaplain," as the holder of the living is officially styled. The election is by vote of the inhabitant ratepayers, and the polling has been carried on amidst scenes of turbulence only capable of being summed up in the one word, "rowdyism." Even as Mr. Dollman's work was passing from the press, the parish witnessed another such contest, the proceedings connected with which led to an offer being made by the bishop of the diocese (Rochester) to raise or provide funds for the endowment of the chaplaincy and the maintenance of the fabric, on condition that the presentation to the living should vest in the diocesan. A meeting of the parishioners to consider the offer was held on the 12th inst., Mr. Thomas F. Rider, "Warden of the Great Account," in the chair. A minority of those present at the meeting, for reasons known to themselves, opposed the motion which was made for referring the Bishop's offer to a representative committee, which was, however, ultimately carried. In the course of the discussion, which must have edified the chairman (well known as a builder, and late President of the Builders' Benevolent Institution), the following dialogue took place, according to the report of the *South London Press*:—

> Mr. Lawson: What was it which kept up a church? (A voice, "An arch,") No, not an arch. Something in architecture. (Laughter.)
>
> Mr. Stafford: You mean the foundation-stone. (Loud laughter.)
>
> Mr. Lawson: No, not the foundation-stone. (Laughter.) Let me see,—the keystone. That's it. (Laughter.) Don't let us take away the keystone.

New Reredos, Cockington.—A new reredos in the parish church of Cockington, near Torquay, was unveiled on the 28th of August. The church, dedicated to SS. George and Mary, is an ancient Gothic building, pleasantly situated in the grounds of Cockington Court. The new reredos, which is a special gift, has been designed by Mr. James Hine, architect, Plymouth, and is in the Late Decorated style. It is made of English oak; the lower parts are enriched by linen panels, surmounted by a carved cornice. Above the altar-table the entire length of the reredos proper is formed, in the main, of seven continuous and connecting canopies. These, in each instance, spring from sculptured angels bearing shields, upon which are emblazoned the various emblems of the Passion. The recessed panel is of chestnut wood, and upon it is painted a representation of the Last Supper. This painting is by Mr. J. T. Fouracre, of Stonehouse, Plymouth. The new reredos has been made and carved by Mr. Harry Hems.

Building Societies.—A return has been issued of an abstract of the accounts furnished by building societies incorporated to the 31st of December, 1880, under the Building Societies Acts. The total number of societies reported upon, of which twenty-three are dissolved and twenty-one are in default, is 1,267. Only 1,015 of them report their membership, which amounts in the aggregate to 372,035. In 1,115 instances the total amount of receipts is returned at 18,694,555*l.*, and in 1,111 cases the liabilities are set down,—to the holders of shares, 21,813,095*l.*; to depositors and other creditors, 14,079,762*l.* In 903 societies the balance of unapportioned profit is returned at 1,104,735*l.*, and in 167 societies there is a balance deficit of 47,209*l.* The aggregate assets of the whole of the societies are returned as,—balance due on mortgage securities (not including prospective interest), 34,847,320*l.*; amount invested in securities and cash, 2,103,060*l.*

The Japanese Theatre.—Mr. Robert Irwin, in his capacity of Hawaian Consul, has just presented a very beautiful drop curtain on behalf of H. M. King Kalakaua to Mr. Morita, lessee of the Shintomiza Theatre. According to the *Japan Weekly Mail*, the curtain is of crimson Japanese velvet. The Hawaian royal coat of arms is embroidered in gold in the centre, and distributed on each side of this in white silk embroidery is the inscription,—"Presented to the Shintomiza Theatre by Kalakaua the First, King of Hawaii, in the second month of the year 2541 (Japanese era)." The curtain was manufactured by Nishimaru & Co. of Kiyoto, and is, we understand, the handsomest thing of the kind that has ever been used in a Japanese theatre.

Old Shrewsbury.—As some workmen were engaged last week in renovating the upper front portion of premises in Wyle Cop, Shrewsbury, occupied by Mr. Taylor, fishmonger, which for the duration of two leases of ninety-nine years were in the occupation of a county family named Lloyd, they knocked off some old thick plaster, and with it the rose of an ancient piece of carving. This led to a careful search being made, resulting in the discovery of a Perpendicular window of the time of Henry VII. in a wonderful state of preservation. The window has three lights with quatrefoils above. Above the window is a curved projection supporting the upper chamber, which has ribs of timber, each of which spring from a corbel. The cornice above the curve is a fine embattled one, and it is thought that above it is a concealed window similar to the one which has just been brought to light. It may be stated that the window discovered is of oak, but exactly similar in design to one in the Abbey Church in Shrewsbury, which is distinctly Perpendicular, and, therefore, there can be no doubt as to the date of that in question. Archæologists are decidedly of opinion that the room in which the window is placed was occupied by Henry VII. on the night before the battle of Bosworth, which decided the fate of Richard III.

Marble Work.—The largest work in decorative marbles yet done in the West of England is making rapid progress at Messrs. J. & E. Goad's Phœnix Marble Works, Stonehouse. The contract which Messrs. Goad are executing is the marble work for the church of the Brompton Oratory, South Kensington, now in progress. The arcading of the whole building will be supported by columns of Devonshire marble, and massive shafts with pilasters of similar stone will uphold the central dome and flank the entrance of each chapel. All the plinths throughout will be of Devonshire black, from the Billacombe and Pomphlete quarries. The dado-work will be of dark mottled, also from Pomphlete. The moulded base of each pilaster is a picked specimen of green marble, which also comes from quarries in Devonshire. The shaft of each pilaster will be of red Devonshire marble, cut in the quarries at Radford. The plinths of the columns, like those of the pilasters, will be of Devon black, the moulded bases of a sienna-tinted variety from Radford, and the columns themselves of a mottled stone from Pomphlete.

The Church Congress of 1881.—The arrangements for the Church Congress at Newcastle-on-Tyne are approaching completion. The Congress opens in the Town Hall on Tuesday, October 4th, and will be in session for four days. The Congress will discuss a variety of subjects of general interest at the present time, amongst them the modes by which religious life may be influenced by art, and the relation of the Church to the social movements of the day, with special reference to trade unions and co-operation. It is understood that Sir T. Brassey, M.P., will treat of the relation of the Church to the social movements of the age, with special reference to trade unions and co-operation. Mr. Beresford-Hope, M.P., is one among the speakers on the subject of the modes in which religious life and thought may be influenced by art.

Memorials of the Dead.—We understand that a National Society for Preserving the Memorials of the Dead in the Country Parish Churchyards of England and Wales is in course of formation, and among those who have joined the society are the Earl Beauchamp, the Earl of Carnarvon, the Earl of Glasgow, the Earl of Northesk, the Lord Talbot de Malahide, the Bishop of Ely, the Bishop of Argyll and the Isles, the Right Hon. A. J. B. Beresford-Hope, M.P., Mr. Stanley Leighton, M.P., &c. It is proposed shortly to hold inaugural meetings in London. Any persons desirous of joining are requested to send their names to Mr. Wm. Vincent, Belle Vue Rise, Lower Hellesden-road, Norwich, from whom all information, with copy of suggested rules can be had.

Sluicing the Pluckington Bank, Liverpool.—Sluicing operations for the removal of this obstructive bank in the Mersey were commenced on Saturday afternoon, at low tide, from three of the new pipes which have lately been constructed at the back of the George's Stage. The sluicing was continued on Monday; and on Tuesday, seven of the pipes were in operation during low water, and the effect on the bank is reported to have been everything that was expected.

The Sanitary Condition of Oxford.—A special meeting of the Oxford Local Board was held on Monday last to consider a letter received from the delegates of the university lodging-houses, with reference to the sanitary condition of their houses. A warm discussion ensued, many of the board considering that their authority had been usurped by the action of the university in calling in Mr. Griffith before they had been consulted; and it was held that many of the alterations suggested by that gentleman were not necessary. Mr. Laker moved that no further work be carried out, as ordered by Mr. Griffith, until his plans had been submitted to and approved by the Local Board; but he afterwards withdrew his proposition and seconded that of Alderman Galpin, "That a committee be formed to confer with the delegates of the lodging-houses with regard to the plans submitted to the Board by Mr. Griffith," which was carried unanimously. Alderman Hughes, the chairman of the Board, expressed his surprise at what had appeared in some of the London papers respecting the sanitary condition of Oxford, for he maintained that the city had been for years past in a very healthy condition, as evidenced by the Registrar-General's returns.

Irish Marbles.—Mr. George Aitchison, A.R.A., in a letter to the *Times apropos* of Irish industries, says that now marble is being largely used for interior decoration, it would be advantageous to have some place in London where all the Irish marbles might be seen. Irish red, Irish green, and Irish black marbles are well known and largely used, but the green Irish porphyry is scarcely known, and there may be many other Irish marbles which would be used if they were known. Although the ordinary Irish green marble, with its streaks of green, grey, and brimstone colour, is not a very effective marble, small portions of it are of the most lovely colour and quality imaginable, looking like dark green seaweed beneath the clear sea. What is wanted is a depôt with a showroom attached, containing large polished specimens of every sort, with the prices per foot marked on; the depôt to contain a good stock, so that the slabs or blocks might be chosen on the spot. It is very disappointing to have to wait until the marble can be sent from Ireland, and then to find that it is totally unlike the specimen chosen. He had a string executed that was to have been green, but it turned out to be grey with hardly a green spot.

Threatened Eclipse of Mr. Spurgeon's Tabernacle.—"General" Booth, speaking in Exeter Hall, at a "Council of War" of the body known as the "Salvation Army," on Monday last, is reported by a daily paper to have aroused much enthusiasm by declaring that the "army" must have built in London "a Salvation Temple, which should be an anti-type of the Temple of Solomon, at a cost of 100,000*l*, which should be open day and night for pilgrims from all parts of the earth." Here is a chance for those who go in for "big things" in the way of competitions; for, of course, for a building of this size (we are told it is to hold 10,000 people), if it ever comes to be erected, there will be a competition?

St. Giles's, Edinburgh.—In the course of the restoration of St. Giles's, Edinburgh, an arched recess has been discovered in the north wall of the Albany aisle, which was built by the Duke of Albany and the fourth Earl of Douglas as an expiation for the death of the Duke of Rothesay. The *Athenæum* says,—"This arched recess is 8 ft. high and 7 ft. wide, with a depth of 2 ft. or 3 ft. On the front of the arch is an exceedingly fine moulding of the thirteenth century, but it is more than half destroyed. Dr. Chambers has ordered the restoration of the moulding, and intends to place a recumbent figure in white marble of the Duke of Rothesay in the recess."

The Iron and Steel Institute will this year hold its autumn meeting in London, and the dates fixed are the 11th, 12th, 13th, and 14th prox. The meetings for the readings of papers on the three first days will be held at the Institution of Civil Engineers, and on the first day the Institute will be received by Sir Henry Bessemer, F.R.S., the president of the Local Reception Committee, and by the vice-president, Dr. Siemens, F.R.S.

Regent-street. — The owner of the new Panton-street Theatre has purchased some large premises in Regent-street, which he intends forthwith to convert into a Jews' synagogue. Mr. Thos. Verity is to be the architect.

The Luminous Paint.—Something seems needed to increase the usefulness of this material, and to give it a wider application. A correspondent writes,—"I brought a bottle of the luminous paint from York, a bottle about 4 in. high and 2 in. in diameter, and nearly emptied it in painting a card-board about 1 ft. long by 8 in. broad; so at present it is an expensive amusement. But the worst part is the nauseous odour! It is most horrible! For indoor work some change must be made, or the paint will be utterly unusable. Moreover, as the luminosity must be frequently refreshed by exposure to strong light, I do not see how it can be made available for dark passages, cellars, and such like." We see it stated in Eastern Counties newspapers that this paint is being used by the Post Office authorities for surrounding the apertures of wall and pillar boxes, and with much advantage in rural districts unprovided with gas.

Topsham Church.—The ceremony of restoring the flags of the Devon and Cornwall Fencibles to the Parish Church of Topsham, where they hung for a period of seventy-two years, was performed on Tuesday last by Mr. S. C. Hall, F.S.A., the well-known author, and only surviving son of Colonel Robert Hall, the commander of the Devon and Cornwall Fencibles, by whom the colours were presented to the church in 1802, when the corps was disbanded. They were removed from the church a few years ago during the rebuilding of the structure, and came into the possession of Major Keating, by whom they were lately presented to Mr. Hall, who has now restored them to the church. We are glad to hear that Mr. Hall, who is now nearly eighty-two years of age, has greatly improved in health during his recent sojourn in Devonshire.

Wistanstow, Salop.—A stained window has just been placed in the north transept of the parish church, in memory of the late Mr. John Hoggins and his wife, and other members of the family. The subject chosen is "The Ascension." The stonework of the window is of the Early Decorated style, with three lights. In the centre light the figure of Our Lord appears ascending, surrounded by a halo of light, while two disciples kneel on the ground beneath. In the two side lights other disciples are seen in different postures of adoration. It has been executed by Mr. John Davies, of the Wyle-cop, Shrewsbury.

TENDERS

For pulling down Cook's Almshouses, Mile-end-road, and rebuilding six houses and shops, for Mr. A. Barnett, Messrs. H. S. & C. A. Legg, architects:—

Longman	£5,199	0	0!

Williams & Sons	3,770	0	0
White	3,764	0	0
Toms (accepted)	3,643	0	0

For alterations, additions, repairs, &c., at the Mansfield Arms, Mansfield-place, Kentish-town, for Messrs. Meux & Co. Messrs. Gardener, Sons, & Theobald, architects. Quantities by Messrs. Selby & Rogers:—

Johnson	£1,450	0	0
Tetmas	1,340	0	0
Nightingale	1,197	0	0
Toms (accepted)	1,116	0	0

For erecting new dwelling-house in Pratt-street, Camden-town, for Mr. Blomfield. Mr. Henry Jacques architect:—

Toms (accepted) £435 0 0

For alterations and additions to stabling of the New Forest Hotel and Posting-house, Lyndhurst Railway Station, for Messrs. Hine Bros. Mr. W. H. Mitchell architect:—

C. R. White	£648	10	0
Thos. Carpenter	594	16	0
Chas. Pike	535	0	0
J. W. Rowland	449	0	0
J. Crook (accepted)	417	0	0

For alterations and additions to Nos. 1 and 2, The Fire Potters Bar, for Mr. G. Mills:—

Eldridge & Gee (accepted).

For a pair of semi-detached dwellings, without foundation work, for Mr. David Tildesley. Mr. Walter Graves, architect. Quantities by Mr. Walter Barnett:—

C. Kelland (accepted) £2,900 0 0

For the reconstruction of wine-vaults, Nottingham, exclusive of foundations, for Mr. H. G. Jalland. Messrs. S. Dutton Walker & Howitt, architects:—

Contract No. 6.

Vickers, Nottingham (accepted) ... £4,787 14 0

For rebuilding Bridge Wharf Brewery, Lewes, for Messrs. Harvey & Son. Mr. William Bradford, architect. Messrs. J. & A. E. Bull, surveyors:—

Patching & Son, Brighton	£4,388	0	0
Howard, Brighton	4,304	0	0
G. H. & A. Bywaters, London	4,059	0	0
Cheesman, Uckfield	3,990	0	0
J. T. Chappell, London	3,976	0	0
Peerless & Son, Eastbourne	3,910	0	0
Card & Son, Lewes (accepted)	3,808	0	0

For alterations and additions to the George IV. tavern, Vauxhall Bridge-road. Quantities by Mr. Edward Crutchloe:—

Boyce	£715	0	0
Foster	710	0	0
W. King & Sons (accepted)	698	0	0
Stiling	681	0	0
Badcock	604	0	0
Quinn	598	0	0

For alterations and additions to the Prince of Wales public-house, Merton-lane, Mitcham, for Messrs. J. Carter Wood, & Co., Westminster. Quantities by Mr. Edward Crutchloe:—

W. King & Son	£395	0	0
Norris	380	0	0
Faulkner	375	0	0
Percy & Peabody	335	0	0
Stiling (accepted)	324	10	0

For the erection of a house, Westcombe Park, Blackheath, for Mr. T. W. Powell. Mr. Edward Robert Robson, architect:—

Higgs & Hill	£3,229	0	0
B. E. Nightingale	3,143	0	0
Kirk & Randall	2,990	0	0
Wm. Tongue	2,960	0	0
Atherton & Latiffe	2,950	0	0
Wall Brothers	2,895	0	0
S. J. Jerrard	2,843	0	0
Wm. Oldrey (accepted)	2,794	0	0

For alterations to the Upper Holloway Baptist Chapel, Holloway-road. Messrs. Searle, Son, & Hayes, architects:—

		Extra if Stone facings.
Southcott & Co.	£2,183	£110
Bamford	2,181	115
Goodman	2,075	85
Dove Bros.	2,015	90
J. Harper (accepted)	1,955	195

For mineral water factory, Holloway-road, for Messrs. Cooper & Co. Mr. G. Corfé, architect:—

Vears	£1,824	0	0
Cross	1,650	0	0
Macfarlane	1,498	0	0
Harper (accepted)	1,342	0	0

For new schools, Gifford street, Islington. Mr. W. Smith, architect:—

Larke & Son	£1,870	0	0
Danford & Langham	1,689	0	0
Mattock Bros.	1,671	0	0
Harper	1,632	0	0
Shurmur	1,583	0	0
Cole & Chant	1,555	0	0
Stevens Bros.	1,548	0	0

For St. Matthew's Church, Brighton. Mr. John Norton, architect. Quantities supplied by Mr. S. J. Thacker:—

W. H. Webber	£13,350	0	0
G. Cheeseman & Co.	12,000	0	0
Goddard & Sons	11,131	0	0

All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, not necessarily for publication.

We are compelled to decline pointing out books and giving addresses.

NOTE.—The responsibility of signed articles and papers read at public meetings, rests, of course, with the authors.

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS TRADE, AND GENERAL ADVERTISEMENTS.

Six lines (about fifty words) or under ..... 4s. 6d.
Each additional line (about ten words) ..... 0s. 6d.

Terms for series of Trade Advertisements, also for Special Advertisements on front page, Competitions, Contracts, Sales by Auction, &c. may be obtained on application to the Publisher.

SITUATIONS WANTED.

FOUR Lines (about THIRTY words) or under ..... 2s. 6d.
Each additional line (about ten words) ..... 0s. 6d.

REPLIES TO ADVERTISEMENTS,
Addressed Box —, Office of "The Builder,"
Cannot be forwarded, but must in all cases be called for, and the Office Receipt produced.

THE CHARGE FOR A BOX IS AS UNDER:—
For "Situations Wanted" Advertisements ..... 2d. per Week.
For all other Advertisements ..... 6d. per Week

PREPAYMENT IS ABSOLUTELY NECESSARY.

**** Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, King-street, Covent-garden, W.C. to

DOUGLAS FOURDRINIER, Publisher,
Addressed to No. 46, Catherine-street, W.C.

Advertisements for the current week's issue must reach the office before THREE o'clock p.m. on THURSDAY.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied *direct* from the Office to residents in any part of the United Kingdom at the rate of 19s. per annum, *prepaid*. Remittances payable to DOUGLAS FOURDRINIER, Publisher, 46, Catherine-street, W.C.

Best Bath Stone.
WESTWOOD GROUND,
Box Ground, Combe Down,
Corsham Down,
And Farleigh Down.
RANDELL, SAUNDERS, & CO., Limited,
Corsham, Wilts. [ADVT.

Box Ground Stone
Is the best for use in all exposed positions, being a well-known and tried weather stone.
50,000 feet cube in stock.
PICTOR & SONS,
Box, Wilts. [ADVT.

Doulting Freestone and Ham Hill Stone
of best quality, in blocks, or prepared ready for fixing. An inspection of the Doulting Quarries is respectfully solicited; and Architects and others are CAUTIONED against inferior stone. Prices, delivered to any part of the United Kingdom, given on application to CHARLES TRASK, Norton-sub-Hamdon, Ilminster, Somerset.—Agent, Mr. E. WILLIAMS, 73, Charlotte-street, Portland-place, W. [ADVT.

Doulting Stone and Ham Hill Stone,
of best quality. Prices and Estimates, including delivery to any Station, on application to
STAPLE & HANN, Quarrymen, Stoke-sub-Hamden, Ilminster. Agent, E. CRICKMAY, No. 4, Agar-street, London, W.C. [ADVT.

Asphalte.
Seyssel, Patent Metallic Lava, and White Asphaltes.
M. STODART & CO.
Office:
No. 90, Cannon-street, E.C. [ADVT.

Asphalte.—The Seyssel and Metallic Lava Asphalte Company (Mr. H. Glenn), Office, 38, Poultry, E.C.—The best and cheapest materials for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds and milk-rooms, granaries, tun-rooms, and terraces. [ADVT.

Immense quantities of
DRY WAINSCOT,
DRY MAHOGANY,
DRY WALNUT,
in all thicknesses.
B. J. HUDSON & SONS,
Whitfield-st., W., and Great Peter-st., S.W., London. [ADVT.

Pure Air and Purified Water: New Light on the Solution of the Sewage Problem.

THE most advanced science of the Middle Ages regarded all things as ultimately referrible to "the four elements." Fire, air, earth, and water were considered to be original entities or principles, and the visible species of the material world were regarded as partaking of fiery, airy, earthy, and watery mixtures. The classification was not confined to the surface of our planet: it was extended to embrace the heavenly bodies. The signs of the zodiac were divided into tetrarchies or tetramenies, the fiery, airy, earthy, and watery signs being always in trine aspect to one another, that is to say, four signs apart; and the planets themselves are spoken of as earthy or fiery, cold or moist.

The discoveries of Dalton and of Cavendish opened the door to a very different appreciation of the elements of chemistry. But some of the old associations yet linger. Above all we are accustomed to speak of the air as something everywhere present, and everywhere the same, "the air we breathe, without it we die."

We are, however, now aware that very great changes have taken place in the composition of the atmosphere, long since our planet was the abode of animal life. As to whether permanent change is still going on, we have no data on which to form an opinion; we can, however, conclude that the waters of the ocean are gradually becoming more salt. We know that in those cases (of which the Dead Sea is the most conspicuous example) in which rivers run into a basin from which the only escape is by means of evaporation, the water continually grows salter. A change of the same kind, however slow, must be occurring in the ocean, to which the rivers are constantly contributing the salts that they wash from their beds.

The effects of storm, tempest, and rain tend to maintain the general unity of condition of the atmosphere. But apart from that difference which is appreciable to the senses, in what we call the change of air from spot to spot, which is more probably telluric than atmospheric in its origin, very great differences exist in the hygrometric character of the air, in different localities, as well as at different seasons. Again, the atmosphere is at times locally loaded with smoke, with miasmata, and with the products of the respiration of animal and of vegetable life; and where masses of men are congregated, as in our great cities, and where walls and barriers prevent the free circulation of air,—above all, in badly-ventilated apartments,—the loading or vitiation of the atmosphere may proceed to such an extent as to make it unfit to support life. We must remember that it was not until chemical analysis had been carried to a high degree of delicacy that it became possible to ascertain either the quality or the quantity of the foreign elements mingled with a vitiated atmosphere. The most subtle test, after all, is afforded by the human lungs; and we know that so slight a change as that of the diminution from 2,096 parts out of 10,000, to 2,075 parts, in the oxygen of the atmosphere, that is to say, of 21 ten-thousandth parts, when the place is supplied by carbonic acid and animal exhalations, is most perceptibly injurious to respiration.

It is thus evident that there is a close connexion between such a subject, which we may call primarily one of an architectural order, as the ventilation of halls and buildings, and the poisoning by carbonic vapours, and by coal gas, and again as the practical manufacture of oxygen. These three subjects of study have been recently illustrated respectively in a French, a German, and an American scientific journal, and brief abstracts of the three papers in question will be found in the recently-issued sixty-fifth volume of the "Minutes of Proceedings of the Institution of Civil Engineers."

That the supply of oxygen gas, whether in that form, or in the state of ozone, is one of the most efficient, perhaps the most efficient, means of restoring the purity of the atmosphere, we think is indisputable. We see the effect of a powerful dose of oxygen in the case of the application of the liquid known as Condy's disinfecting fluid, the action of which on tainted water or sewage is so direct and certain. In fact, for purifying water from organic pollution, the supply of oxygen may be regarded as the one specific. This is the secret of the action of gravel or sand in purification of polluted water. Oxygen is admitted into direct contact with the particles of foreign matter in percolation, and, in point of fact, consumes them. So it is if oxygen is thrown into the polluted fluid chemically, as by means of the fluid we have named. The action of the oxygen is the same, whether it be mechanically or chemically supplied. But supply of oxygen to a vitiated atmosphere has been hitherto less studied than its application to polluted water.

The question of cost of production has stood much in the way of the utilisation of oxygen for sanitary purposes. M. E. Guitton, who is the inventor of a new process for the production of oxygen, contemplates the manufacture of his gas at the price of half a franc per cubic mètre and less in large quantities. This is just one per cent. of the price which the French theatres now pay for a supply of the gas. A cubic mètre contains 35·35 English cubic feet. Thus, ordinary coal-gas, at 3s. 3d. per 1,000 cubic feet, costs about 1½d. per cubic mètre; so that M. Guitton proposes to reduce oxygen to less than the price of coal-gas. It is evident that, if this can be done, an immense step will have been taken in the progress of sanitary application.

It has long been known that barytes possesses the power of absorbing oxygen from the atmosphere at a certain temperature, and giving it out again at a higher temperature. But the practical difficulty that has hitherto interfered with the utilisation of this property is, that after a certain number of repetitions of the process (about ten) the material used becomes inert, and incapable of continuing the same operation. The improvements introduced into the process by M. Guitton consist in (1) the preparation of the air, by the removal of carbonic acid and the supply of moisture, in order to render it easily decomposable by the barytes; (2) the use of pumps or fans to facilitate the peroxidation of the barytes; (3) the employment of a vacuum, or exhauster, for the extraction of the oxygen from the oxidised barytes; (4) the application of great heat, under the guidance furnished, by a special pyrometer; and (5) the preparation of the barytes itself.

The process is now being carried on at Passy. With an average of ten charges per day, forty cubic mètres of oxygen are obtained from 100 kilogrammes of barytes. The gas obtained was 95 per cent. pure oxygen. The 5 per cent. remainder was nitrogen, probably furnished by the atmosphere, owing to some defects in the apparatus. The cost was 0·619 franc per cubic mètre; but with increased production it is estimated that it can be reduced to 0·127 franc per cubic mètre, or 3½d. per 1,000 cubic feet. Oxygen made from chlorate of potash and binoxide of manganese costs 12 francs per cubic mètre.

The uses to which an economic supply of oxygen can be advantageously put are many. If it be applied to the combustion of charcoal, or of mineral oil, a splendid light is produced, at about one-third the cost of Paris gas. As to its application to the purification of the atmosphere, whether of rooms or of streets, we have to await experiment. But it is, in our opinion, a matter deserving the most serious attention to consider how far the boon which the talent of M. Guitton has supplied to industrial chemistry may lead to a solution of the most pressing and most perplexed of the sanitary questions of the day.

Of that foul and noxious flood which the Metropolitan Board of Works are now constantly pouring into the Thames, the poisonous and useless element is the organic matter, in various states of decomposition. Of the solid and liquid elements of sewage, apart from the water used as a carrier, the organic portion forms respectively 4·62 and 4·15 per cent., in weight. The ordinary dilution (exclusive of that by storm-water) is from 90 to 100 to 1. Thus out of 10,000 parts of weight of ordinary sewage, the poisonous element may be taken as 4½ parts. If this be removed or destroyed, the other foreign matters, mineral and gaseous, are not only unprejudicial, but have a chemical value of something over 4s. per unit of population per annum.

And the sewage utilisation problem is, how to extract this fertilising matter at a less cost than its agricultural value.

So serious has every experimenter found the cost of such extraction to be, that the idea of sewage utilisation, except under very favourable conditions, is gradually losing supporters; and it is indeed felt that the endeavour to secure a commercial value has greatly interfered with the progress that might otherwise have been made in the more urgent requisite of disinfection. For a considerable time our own opinion has been more and more steadily pointing to the conclusion that precipitation, filtration, and actual combustion of the solid deposit of sewage would have to be resorted to sooner or later. And as to this, the fact that the poisonous organic matter is itself combustible has led us to consider how far dried sewage may be made to consume itself, with but little extra fuel.

But if it be possible to drive through a volume of sewage a current of oxygen gas, the combustion of the organic matter will be effected in the most ready and complete manner. In point of fact, if a sufficient quantity of Condy's fluid were mixed with a stream of sewage, the results would be admirable. The barrier, of course, is the expense. The possibility of supplying pure oxygen is therefore to be regarded, not so much mechanically as financially.

Here there comes in the question, if oxygen can be supplied at less than the price of ordinary coal gas, does it not afford us what we require? Under any circumstances, it is the combustion of the organic matter which is the great aim we have in view. Is it likely that this organic matter, when once it has been collected in great unmanageable reservoirs, can be more cheaply destroyed in any other way than by admitting to it as it exists in solution or mixture in the sewage the dose of oxygen necessary for its combustion?

As to the cost, it is, no doubt, considerable. But the point to consider is,—can the object be attained by any cheaper method? That we shall long go on polluting the Thames without stint we do not conceive to be possible. The nuisance is becoming intolerable, and pestilence will follow if it is not abated.

Ordinary albuminous matter requires about nine times its own weight of oxygen to consume the hydrogen and carbon which it contains. In 10,000 gallons, or 100,000 lb. of ordinary sewage, there is, as we have seen, about 45 lb. of organic matter. To consume this is requisite 400 lb. of oxygen. Now, 11·89 cubic feet of oxygen weigh 1 lb., so that 4,760 cubic feet of this gas will be required to consume the organic matter in the 100,000 lb. of sewage. The cost of the gas, on M. Gaitton's showing, will be about 13s. 6d. The 10,000 gallons of sewage may be taken as roughly equal to the proportion per unit of population; and the chemical value of the mineral elements of the sewage has been some time back estimated at 4s. 8½d. per unit of population. Thus if the actually poisonous matter be destroyed by the admixture of oxygen, the mineral elements will remain in a condition in which they may be dealt with without danger and without disgust, and at least a third of the cost of the process may be recovered from its results.

This is not so brilliant an outcome as has been often anticipated. But the question is, can anything be substituted which is cheaper, and equally likely to be effective? We desire to put forward the suggestion with all reserve. It is one which demands not only reflection, but experiment, in order to determine its value. But we confess that a great reduction in the price at which oxygen can be produced seems to us, at all events, to cast a ray of light in the direction in which we have been for some time straining our eyes. It is this ray that seems to us to emerge from the process of M. Gaitton. We may be wrong. We may be too sanguine. But we feel convinced that the idea is one which should not be either scouted or neglected. It would, no doubt, require sustained experiment on a considerable scale to ascertain how much more than the quantity of oxygen that on paper would be fully equivalent to the combustion of all the organic matter in a given volume of sewage would be practically necessary in order thoroughly to purify that volume. The bit of experience which is most conclusive in our minds is the magical action of the fluid we have mentioned, which is much too costly for use on a large scale. But we call the attention of those of our readers who, like ourselves, have been long studying this great problem of civilisation, with good hope of some wholly unexpected solution. And we invite the ingenious author of the process (whom we only know from the pages of the "Resumé de la Société des Ingénieurs Civile," and from the "Minutes of Proceedings of the Institution of Civil Engineers"), to add any contribution that his own experience can suggest to our attempt at a fresh step towards a definitive solution of perhaps the most vexed problem of civilisation.

THE SOCIAL SCIENCE CONGRESS.

It is to be hoped that the attractions of Irish hospitality, as well as the more serious interest attaching to everything connected with that part of the Kingdom at present, will avail to counterbalance the disadvantage of the rather long journey which London members will have to take for this year's congress. It has generally been found that the attendance of the London contingent of the members is inversely in proportion to the distance to be traversed, a consideration which, we believe, operated against the attendance last year at Edinburgh. It may be said, however, that the capital of Ireland seems at present a very appropriate and suggestive quarter in which to discuss the graver problems of social relations, and we have reason to suppose that the brief and comprehensive theory of the relative positions of England and Ireland which was formulated by Moore,—

> "On our side is virtue and Erin,
> On theirs is the Saxon and guilt,"—

is not accepted by the Dublin promoters of the Congress as an accurate representation of the position. The long list of names in the local committees seems to indicate a considerable interest in the matter, at all events in the Irish capital.

The special questions in the legal and educational departments seem to be of serious import and of more than usual interest; on these we are not called upon to comment. But we cannot look without special interest at the announcement of the first question to be considered in the Economy and Trade Department, as to the results that may be expected to arise from the extension of the system of participation by labour in the profits of manufacturing, agricultural, and trading enterprises. We have long approved this system and desired its extension, and have often recommended it, notwithstanding what has been said as to failures, as the most promising solution of the problems arising from the at present conflicting interests of employers and employed, and we cannot but hope that some decided stimulus to the further extension and adoption of the system may result from the discussion of the question at Dublin,—at all events, that its value and hopefulness as a means of promoting true mutual understanding between labourers and capitalists may be brought home to many who have, perhaps, not duly considered the subject before. The third question in the same department,—What industries could be advantageously developed in Ireland, which from natural causes are specially suitable to the country?—is one of the greatest and most special interest to Ireland at this moment, though we fear we must not be too sanguine in expecting any very large or immediate results from it; still, some suggestion of value may be thrown out, which may bear fruit at a favourable moment.

The special questions for consideration in the Health Department deal entirely with the legal aspects of sanitation; they are not concerned with mechanical means of ensuring healthy conditions, but with the legal means of controlling the population so as to lead them in the paths of righteousness as contemplated from a sanitary point of view. The question whether hospitals should be placed under State supervision, which is the first on the list, is one in regard to which we should feel very doubtful whether any but a qualified assent could be given. The question here, as between the advantages of private and of Government management, suggests somewhat the same kind of *pros* and *cons.* as the question of Government interference with railway management. In regard to the latter, it is believed that the interests of the public are better served by allowing each company to adopt its own manner of working and its own plans of construction than by the Government imposing any uniform system upon all. So with hospitals: we imagine that no persons are so desirous to keep hospitals under the best sanitary conditions as the medical superintendents themselves, and that it would be much more desirable to allow scope for the exercise of individual judgment and for reasonable liberty of experiment than to impose a set of hard-and-fast rules on hospital authorities. Government inspection, if adopted, would be better confined to advising and reporting in the main; though the results of a general survey, extending over some years, by competent Government officials, might be very well and advantageously summed up in a general code of recommendations derived from the total result of this experience. To the third question,—Is any further legislation necessary to more effectually prevent the overcrowding of dwelling-houses?—we imagine a very decided affirmative will probably be returned. It seems certain at least that either the present legislation in itself, or its practical method of operation, is deficient in efficacy to check this evil.

Of the three questions forming the special subjects for discussion in the Art Department, one is of a practical and business character, and the other two are more vague in their objects, and touch more nearly on the ever-vexed question of "taste." The practical subject is that of copyright as regards music, painting, sculpture, and the fine arts generally, considered in relation to the Bill on the subject to be introduced into the House of Commons. We expressed a part of our mind upon the difficulties in connexion with artistic copyright some time since (see *Builder* for February 15th, 1879). The subject is one of the most awkward to deal with in a legal manner, partly on account of the difficulty in defining what constitutes infringement of copyright in regard to a work of art, and also the difficulty of settling what is equitably due both to artist and purchaser. We may call attention to the fact that music, although grouped with arts of design in the heading of the question, in reality does not stand on the same footing, but is under conditions much more nearly allied to those which operate in the case of literature, and might better be treated in that connexion. A printed piece of music is like a printed book; it can be said at once whether it is a piracy or whether it is not; but a design is a more delicate matter. It may be copied so as to get all that is of most value in the idea and execution, and yet so as to evade the charge of actual copying; or it may be reproduced (which is what the artist dreads just as much) in what is intended as a faithful copy, but so clumsily executed as to libel the original work, and injure the repute of the artist with those who have not seen the original. With this chance hanging over him, the artist not unnaturally wishes to prevent any one making copies, save under his own supervision,—a matter which, in the case of works that are accessible for public inspection, is very difficult to accomplish, and the most rigorous laws on the subject may bring him no nearer intercepting the transgressors. The purchaser has his interests also, which are of a more commercial kind, but not on that account any more easily defined and protected by law. The purchaser has paid money for the picture, or statue, or whatever it be, and having done so he can place it in his private house, in his inner chamber if he will, and have the full and uninterrupted enjoyment of it; but he demands more than this: he demands that no one else should have the enjoyment of it,—in other words, that the artist shall not furnish a similar painting or statue to any one else. If the question were argued on artistic grounds only, this attitude would hardly be defensible at all: it would be properly regarded as a selfish and dog-in-the-manger policy; but the subject is complicated by the fact that paintings cost money, and represent, therefore, a money value which the owner may some day wish to realise, or even be compelled by circumstances to endeavour to realise as far as possible, and he has then some reasonable ground of complaint if he discover that, say, three other persons have replicas of the painting, and that one of them obstinately claims that his own is the original, and thereby brings down the value of the real original at a time when its owner is very desirous to realise as much of that value as possible. This seems, perhaps, a very low view to take of the value of a work of art, but the value of works of art has its commercial side, and there can be no question that artists have occasionally very unfairly ignored this fact in their production of replicas; and that, although the question of artistic copyright is of more importance to the artist than

to any one else (since it touches him in repute as well as in pocket,—"who steals my purse, steals trash," &c.), still it has its importance to the purchaser, whose interests ought not to be ignored.

The second special question,—What should be the relations of painting and sculpture to architecture?—seems to involve two questions, that of the province of the architect, and the relation in which he is to stand to the sculptor and painter, whether as overlooking and controlling their additions to the building, or whether merely preparing a frame for them to fill in as they please; and the relation of architecture itself to sculpture and painting, and how far it is to be regarded as a genuine "art" independent of them. The question touches upon some interesting points in regard to the practice of architecture, and of what may be called monumental art generally. The third question, as to the influence of the annual exhibitions of sculpture or painting upon the public taste, appears rather vague, but it is quite possible to treat it so as to lead to some practical results,—at all events in regard to one point (which has been before touched upon in the Art Section), viz., the desirability of some control being exercised over the at present unlimited scope afforded to Royal Academicians to hang anything they please and as long as they please,—a liberty the unchallenged indulgence of which has already led to strange and even ludicrous results in some of the annual Academy Exhibitions, and which we imagine some of the more eminent members of the body would be very glad to see judiciously restricted.

There is, at all events, plenty of scope for discussion in these three subjects in the Art Section; and Sir R. Stewart, the Professor of Music in Trinity College, Dublin, is also to read a paper on musical education, and there will, no doubt, be other subsidiary papers not yet officially announced.*

THE MIDDLESBROUGH JUBILEE.

Commemorative of its commencement, the busy town of Middlesbrough-on-Tees is proposing to celebrate its jubilee. It intends to unveil a statue of Mr. Henry W. Bolckow, one of the chief of its ironmasters in the past, its first mayor, its first member, and the head of that firm which played so great a part in the development of the town. It honours the memory, also, of Mr. John Vaughan, Mr. Bolckow's partner, and of Mr. Joseph Pease, its projector. In the celebration Lord F. Cavendish takes a principal part, and Earl Granville, Sir Thomas Brassey, and other distinguished men, are to be present; whilst, subsidary to the chief feature, there are to be processions and fireworks, electric-light displays, and a banquet for the chief guests. It is slightly over fifty years since the commencement of Middlesbrough, but the delay in the holding of the jubilee enables the day to become also the occasion of the unveiling of the statue, and of the presentation of portraits.

Middlesbrough was projected by the promoters of the first public railway as a port for the shipment of coal, and rather over fifty years ago the first shipment was made. On that foundation the town was commenced, the site at the time of the purchase of the land being at the best agricultural land, and the population under two score. But, under the influence of the directors of the Stockton and Darlington Railway, the young town grew, attracted one or two small manufactures, and at the end of the first decade, after its practical commencement, it had a population of 5,709. In the next decade, the census of 1851 showed an increase only to 7,893, although the iron trade had been introduced in a small way into the town. But the supplies of ironstone in some of the lead and coal mining districts of Durham had given out, and as the demand for iron increased with the development of the railway system, ironmasters had recourse to the iron deposits of the southern part of Cleveland, and sought for the continuation of these deposits in the northern part. Here, rather over thirty years ago, that discovery was made which changed the fate of Middlesbrough,—the outcrop of iron being "found" in the high ground flanking the river Tees to the east of Middlesbrough, by Mr. John Vaughan, one of the partners in the firm of Bolckow & Vaughan, the leading ironmasters. The utilisation of that discovery changed Middlesbrough from being a mere coal-shipping port to one of the chief centres of iron production and manufacture in the world; made millionaires of the two principal ironmasters; and developed what had been a remote and isolated district until it is one of the most populous and prosperous towns in the North. By 1861, the population had risen to 18,273; in 1871 it was 39,434; and the recent census has shown that that growth continues, the return giving the present population at 55,978.

Before the discovery of iron at Eston, the total production of the north of Yorkshire was under 100,000 tons yearly; but the cheaply-wrought ironstone close to abundant facilities for its disposal has so stimulated the trade that the production has risen almost without a check until last year the extraordinary quantity of 6,441,783 tons was extracted from the Cleveland mines. No blast-furnace existed in Cleveland or on the banks of the Tees at the time of that discovery; but there are over 100 now,—a vast smelting plant which is larger on an average, and more productive, than that of any other iron-making district. And there has been in the half-century a growth as full, in comparison, of finishing ironworks, of foundries, of shipyards, and others of the iron-consuming industries, so that the whole of the north-east of England has felt to the full the benefit that has arisen from the growth of the great iron-producing and manufacturing centre. In the past decade, the district felt the force of the depression doubly, and that because, in addition to the general causes, there was the special effect arising from the fact that Cleveland iron was unsuitable for the steel manufacture. Continuous efforts have resulted in the resort to the dephosphorisation process, by which the vitiating elements are eliminated from the Cleveland iron in the Bessemer converter, and it is thus adapted for the manufacture of the more enduring and increasingly preferred metal. And thus there has sprung up, and is springing up, in the Cleveland district a newer industry, which is largely contributing to the removal of the effects of the depression of four years ago.

The half-century whose passing is to be commemorated has built up the chief town in Cleveland and the great industry on which it and others depend, and given to it all the essentials of vigorous town life. The rateable value of the thrice-extended borough has been raised in the five decades from a few pounds to 200,000*l*. Its School Board has provided accommodation for 4,310 pupils; its free library numbers many thousand borrowers lately; its gasworks make 166 million cubic feet of gas yearly; and the Middlesbrough part paid in the last half-year 15,114*l*. for the water it needed from the jointly-held waterworks; whilst the inadequate supplies are forcing the adoption of a vast scheme of reservoirs in Baldersdale. These are indications of the growth of the iron town, which boasts that it is the chief centre of iron production, and owns the greatest steelworks in the world. To those who fostered that trade, and gave to it the abundant supplies of cheap minerals on which it is built, it has long professed gratitude, and takes advantage of the jubilee celebration to put it in enduring mementoes. It has had its checks to prosperity in the dulness that it knew down to a year ago, but it is now about to make a further spring forward, and thus it is that the jubilee celebration may be said to divide the past from the future of Middlesbrough, and to separate the small coal-exporting town which has become the centre of the crude iron trade from that of the future, the dependence of which will be, it is in every way certain, upon some of the forms of steel manufacture, and probably on that of the Bessemer trade.

Birkbeck Literary and Scientific Institution, Southampton-buildings, Chancery-lane.—The 59th session of this Institution will commence on Monday next. Evening classes, which are open to both sexes, are held for the study of Ancient and Modern Languages, Mathematics, Natural, Applied, and Mental Science, Literature, History, Law, Art, Music, &c.; in fact, every opportunity is offered at this Institution for students to prepare for any occupation or profession. The fees are very moderate. The committee again appeal for contributions towards the new building.

BUXTON.

Remembrances are brought up at Buxton of those mountains Bunyan speaks of, where the rivers flowed with "fine trees on both sides," the meadows "are green all the year long," and where "all things are managed to the supporting of the weak." It is, indeed, the paradise of the invalid, but it is more than that,—it is the resort alike of the valetudinarian and of the pleasure-seeker; and hence lovely youth and crabbed age together press the floor of the pavilion, or watch the lawn-tennis players in the grounds. It is long since Buxton established its fame as a health resort, and to it there comes, summer and winter, a constant stream, to exercise the bath chairs that darken the front of the Crescent, or to wander in pairs by the banks of the Wye. The old Romans, who are supposed to have known the baths, were the predecessors of those who three centuries ago deemed them the most fashionable resort in the kingdom. Dukes and earls have been the benefactors of the little town. The ill-fated Queen Mary visited it in her imprisonment, and left on the window of the old hall her tributary farewell to the "milk-warm waters" of Buxton, and with the patronage of kings and queens the town rose into that pre-eminence that it still holds. Its attractions are natural and acquired. It is in the midst of some of the most noted scenery of Derbyshire; it has near to it some of the quaint and pretty rural nooks that attract visitors, but do not themselves provide for the continuous and comfortable stay of strangers; it has added to the charms of wood and water that it possesses; and it has springs and baths the medicinal value of which has been long esteemed. To these, the dukes of Devonshire in the past have added much. That fine pile, the Crescent Buildings, on which a century ago 120,000*l*. were spent; the terracing,—to coin a word,—of the rising-ground in front, under the direction of Paxton; the damming-up of the Wye till its waters form pools and cascades; the designing of the gardens and grounds of the Improvements Company; the erection of churches, chapels, and hospitals; the enlargement of ancient hotels, and the growth of villas,—these are the indications of the growth that chiefly in the last few decades has marked Buxton.

In its season there is no more perfect panorama of life in its many stages than is to be seen in this Derbyshire haunt. By the side of the perambulator is to be seen the Bath-chair of age that clings to life with a tenacious grip and hobbles to the pure air around these "delectable mountains" to stretch out its latest days; whilst around them are all the intermediate stages. In the early morning the number of Bath and invalid chairs drawn up in front of the baths, with their attendants, is a revelation of the popularity that Buxton possesses for invalids; whilst the tripping of fleet feet along the arcade in rainy weather, or the light laughter that in sunny days makes musical the paths that lead to Diamond-hill,—these portray the pleasures of youth in the ancient health resort. For all ages Buxton caters. It has its rink for the youth, its pavilion and gardens for the middle-aged, its baths for the infirm. When music arises "with its voluptuous swell" in pavilion or garden, there are revelations of the fashion of the visitors near; when sounds the bell there is along the colonnade a troop of the distinguished, and their vulgar followers, sufficient to make the old hotels gay, and to people the rooms of many of the villas. Buxton has recognised the fact that it needs to add to natural beauty the essentials of comfort, and of pleasant, social life, and these draw from a large and growing area the visitors on whose patronage the place depends. For it is a place apart from manufacture, and where commerce presents only the modest guise of an attendant upon pleasure. In the gray streets of Buxton, trade, in its ordinary sense, does not enter,—the neat shops are the temples of ministers unto the wants of fashion, and the trains that enter the station bear the invalids or the pleasure-seekers only. It offers to these pleasant society, comfortable homes, a retreat alike from the cares of business or the jading life of fashion in great cities. Away from the flutter and frivolity of Mayfair,—from the stress and strain of brainwork in Westminster, or from the guidance of great concerns in the manufacturing regions, this little nook,—an hour or two apart, but with the quietness of years between,—gives freshness in its valley and "knits up the ravelled" skein. All around it is the wonderful scenery of the Peak country,—

a

* A meeting of the Council of the Association will be held on Monday morning next, at Trinity College, Dublin, for preparatory business, and in the evening of that day the president, Lord O'Hagan, will deliver the inaugural address.

valleys such as that of Edale, caverns such as those of Castleton, mountain passes like Winyates, bleak moors like Millstone Edge, quaint villages like Eyam, where ancient customs die slowly, haunts of the artists such as Millersdale, resorts of the curious such as Haddon Hall, and that boast of Britain, Chatsworth. It is, then, no wonder that to this once solitary spot,—still retired from the stress and the struggle of life, there come increasingly those who desire to hoard the little strength left them, and those also who steal a brief respite from the struggle. Other and newer health resorts rush into a bourgeois popularity, and by dint of the blazoning of trumpets rise and fall in the fluctuations of fortune and trade, but this gem of North Derbyshire is secure in the patronage that its ancient fame and its present attractions give it, and all the year it draws to itself a distinguished circle.

FRENCH ART INDUSTRIES AND FOREIGN COMPETITION.

There has been, for some time past, a gradual dissatisfaction growing up among the rising artistic notabilities of France; an infinitesimal number of men have even ventured to opine that there was something wrong in France, after all; and the foremost promoters of art for art's sake, of art in every department of life, have discovered that in the home of the cold and calculating islander who loves nothing but his shop and his money-bags, there is an institution deserving mention, — nay, deserving imitation. Need we say that the institution in question is South Kensington? The men who have gathered round the founders of the French Museum of Decorative Art are in advance of their countrymen, and are anxious to see established, throughout France, schools after the pattern of our South Kensington schools. The establishment of schools such as those of England, of Austro-Hungary, of Bavaria, of Russia, of Belgium, is the great cry of the advanced artists in France. We were not surprised, then, to read in the *Review of the Decorative Arts* (*Revue des Arts Décoratifs*: A. Quantin, 7, Rue St. Benoît, Paris), an extremely large-minded and circumstantial article, which the author entitled, "A Danger," and in which he gives the French art-world a few serious and timely hints. He tells Frenchmen that they have for too long taken their supremacy in art as a matter of course. It has been said from time immemorial that France is the home of art, that Paris is the capital of taste and cultivation, that Paris leads the universe! All men have not taken this super-excellence for granted, however; has not Matthew Arnold said,—

"France, famed in all great arts,—in none supreme"?

Moreover, as we have pointed out, it is actually from a Frenchman that we have the cry of alarm respecting the falling-off of art-products in the "capital of art."

M. Saint-Juirs, in the *Review of the Decorative Arts*, asks one or two trenchant questions. Are the French people really the first artists in the world? What is their absolute and relative art influence? Is their art-power increasing or decreasing? Are they losing or gaining ground? Have they anything to fear from competition? The only manner in which these questions can be answered, says M. Saint-Juirs, is by figures; thereupon he plunges boldly into a perfect wilderness of figures. With regard to the fine arts, figures are easily supplied by glancing at the books of the *Salon*, which is the French equivalent of the Royal Academy show; while with regard to figures respecting art applied to industry, the accounts kept by the Customs authorities furnish all the information necessary. We know that, in the department of Fine Arts, 416 foreign artists exhibited at the *Salon* of 1880, side by side with 1,439 French artists. The fact is significant enough, says M. Saint-Juirs, but is by no means as telling as the result of the inquiry into the state of commerce with regard to industrial art. Nothing could be more instructive and interesting than the figures brought forward by M. Saint-Juirs; and he states very precisely the condition of the industrial art imports and exports in 1859,—that is, before the Free Trade reforms were instituted; and in 1880.

In 1859, France imported manufactured articles (not including food products and raw materials, in which no art is displayed) to the value of 2,464,000*l*. In this total, all that represents drawing, engraving, painting, sculpture, is worth 1,000,510*l*.

In 1880 the French imported manufactured articles to the value of 19,937,880*l*., in which sum artistic articles stand for 5,919,240*l*.! The development of foreign art industry is indisputably felt in these figures, and it is not strange that the French should be alarmed at the decrease in French supremacy.

It would be too long, M. Saint-Juirs observes, to go into all the figures; but he gives a summary of the imports of the principal articles in 1859 and in 1880:—

	1859.	1880.
Chinaware and stoneware	£9,008	£176,560
False stones, enamels, stained glass	17,015	114,998
Wall-paper	23,105	56,810
Books	96,442	176,765
Engravings and lithographs	14,194	253,737
Cut coral	8,757	68,361
Jewelry and gold work	10,840	218,040
Artistic weapons	40,7?2	106,141
Furniture	39,165	189,865
Curiosities for art-collections	81,510	426,164

Tissues are not included in this list: the writer considered that they deserved a special paragraph. His figures respecting tissues concern, of course, the brocaded, embroidered, printed stuffs, and laces,—there is no question of any materials in which art is not employed,—and they show, in spite of the great falling off in two departments, thread lace and Indian cashmere shawls, a considerable increase in importations of tissues. In 1859, the tissues imported were valued at 579,285*l*.; in 1880 the sum had increased to 3,589,218*l*.; and these figures are added to the total imports already mentioned.

To turn to the exportation side of the matter, it will be seen that the total export of French manufactured articles in 1859 was valued at 56,116,000*l*., of which sum, 26,619,400*l*. represented the worth of the artistic products. In 1880 the export of French manufactured articles had reached the figures of 74,034,560*l*., in which sum artistic products were represented by 30,644,920*l*. Therefore, while in 1859 the artistic products figured in the total exports at the rate of 47 per cent., in 1880 they reached only a figure of 41 per cent. of the total exports.

These figures are of the utmost importance, as M. Saint-Juirs points out; they are significant, and should not be disregarded by the Frenchmen who are always ready to cry, after the manner of M. Alfred Assolant, that a Frenchman has nothing to do but to remain in France, a thorough Frenchman, and every honour, every distinction, will come upon him as a mere consequence of his nationality. Frenchmen of this type would be benefited by the sober study of the figures brought forward. Here is the broad fact, undeniable, incontrovertible; in 1859, the French imported artistic wares of all kinds to the value of 1,579,795*l*., and in 1880, the imports had reached the value of 9,508,464*l*. Compared with these figures, the increase of the art-wares exports during the stated years, from 26,619,400*l*. to 30,644,920*l*., seems small indeed. From 1859 to 1880, the exportation of art-wares has, therefore, increased at the rate of 15 per cent., while the importation of art-wares has increased at the rate of 488 per cent.!

The exportation of certain classes of art-products has sensibly diminished. The export of splendid silk materials, the brocaded silks, embroidered and stamped silks and velvets, &c., which were the glory of Lyons, has dwindled to a very low state; linen artistic stuffs have decreased, and the same may be said of art copper-work, cut coral, playing-cards, and china. The startling decrease in the export of china is, however, compensated by the increase in the exports of stone-ware, terra-cotta wares, &c. In many departments there has been, of course, a fair increase. The exports of art-bronzes have nearly doubled, while the exports of sculptured marble have more than doubled. Goldsmith's work and jewelry exports have almost quadrupled; and art-furniture exports have just about doubled.

These figures, gathered together and classified by M. Saint-Juirs, with great ability and impartiality, show indubitably that art industry is progressing at a greater rate in other countries than it is progressing in France, and that a serious competition has been growing up in the lands that the French have been content to consider destitute of art. There are many things to be considered while glancing at this evident discomfiture of French art. Are the imported art-products really works of art? Do they display serious culture, genuine feeling for art? If they do, they undoubtedly constitute a real menace to French supremacy. If, on the other hand, these imported articles are bad as to design and colour, then they must degrade the national taste. The foremost among artistic Frenchmen are inclined to believe that the art-industry of their native country is being lowered, is losing some of the exquisite taste of design and workmanship which has been for years its hall-mark; and they declare that the decadence is due to the urgent need of art schools and special museums, where the young idea may be ably tutored and trained in the way it should go. They demand for France the "vulgarisation of art-teaching,"—to use the expressive term of an enthusiast of some thirteen years ago; and they do their best to remind the French people how at recent exhibitions it was shown that England was on a level with France in the furniture and china departments,—that Austria was on a level with France by reason of her bronzes,—that Italy was on a level with France by reason of her glass ware. Japan is becoming a dangerous competitor, and Belgium and America are making giant strides; and France must make up her mind to give her workmen a complete artistic education, and better opportunities of widening their intelligence and increasing their knowledge. Some Frenchmen assert angrily that France has been despoiled of her native industrial art-workers, who have found homes in other lands. It is quite true that French artists of all descriptions have settled in foreign countries, and notably in England; but it is also true that the points which the intelligent and highly-skilled workmen appreciate in foreign countries, and which they have never as yet enjoyed in their native land, are political liberty and good pay.

THE THAMES AND MILFORD HAVEN: DOCKS IN BOTH HARBOURS.

In our recent notice of the project for the creation of new tidal docks for London, we referred casually to the noblest harbour in the British isles, if not in the whole world,—Milford Haven. The publication of the "admirable scheme for providing deep-water dock accommodation for the port of London," has called forth from the secretary of the Milford Docks Company some remarks to which we are happy, not only to call attention, but to add some emphasis from long and intimate acquaintance with the noble Pembrokeshire harbour.

Milford Haven, Mr. Hood remarks, is 170 miles nearer New York than Liverpool, and 264 nearer than London. Such comparative measurement may be widely extended, and continually to the advantage of Milford. Any one who will take the trouble to turn to the terrestrial globe will see that Milford Haven is, in point of fact, the maritime centre of the world. That is to say, that if we seek the point from which the greatest number of ports can be reached by the shortest voyage, that point is the entrance of Milford Haven. Once out of the narrow channel that admits the sailor within St. Anne's Head, a vessel is well at sea,—is in mid-ocean. As an instance of the convenience of Milford, in days when sailing-vessels played a greater part in commerce than is now the case, we can mention a fact within our own personal knowledge. In 1855 a small cargo of railway materials was despatched from Neyland, near the head of Milford Haven, to Lisbon. The consignees wrote in due course by the day's mail to advise the despatch. The little brig arrived at Lisbon before the letter of advice, aided by the services of railway and steam-packet for the carriage of the mail! For sailing-vessels, indeed, the advantage afforded by Milford, when the wind is in fifteen out of sixteen points of the compass, has been long known to the sailor. Steam-vessels do not so much depend on wind and tide as did sailing-vessels; but the advantage of position in shortening voyages is none the less, and it is one on which the navigator may safely calculate at all times.

On the 15th of the past month, we are glad to learn from the letter of Mr. Hood, the largest caisson ever built was successfully floated across the graving-dock entrance of the new docks at Milford, effectually closing in sixty acres of water. There is not, the secretary to the Milford Docks adds, to his knowledge, "an instance on record of so large an extent of water space being closed in by a single caisson." The caisson is 100 ft. in length, 15 ft. in breadth, and 48 ft. in height. Its weight is 48 tons. The graving-dock is 710 ft. long, 96 ft. wide, with 34 ft. of water on the sill at high water.

By the aid of caissons it can be used by ships up to 700 ft. in length, and can also be used as a lock entrance,—an important feature in view of the size of some of the vessels now being constructed for the American trade.

The Milford Docks will have a water area of thirty acres available for large ships, and quay-berthing accommodation to the extent of 9,840 ft. All the latest appliances for coaling, and for loading and discharging cargoes, will be provided. It should be remembered that the Haven itself forms a natural basin in which the whole navies of the world might safely ride in any weather. There is no place in England in which artificial docks might seem to be so little required; and the fact of their having been now constructed to such an extent, with such facilities for entrance from the harbour, presents an accommodation to commerce such as, we should think, is nowhere else to be found. As far as the outer world is concerned, Milford has the advantage over any port in the United Kingdom, both for position and for unlimited capacity, as well as safety. To this is now added, the convenience of floating basins allowing of easy loading and unloading.

The journey to London by rail can be performed in six hours and a half, and when the Severn tunnel is completed, the distance will be considerably shortened. Direct communication with Manchester, Birmingham, and the Midland counties, as well as with the industrial districts of North Wales, is also commanded by railway.

It is a curious coincidence that on the same day on which Mr. Hood's letter calling attention to Milford Haven was published, there appeared an invitation, to persons concerned in shipping, to inspect the *Great Eastern* steamer, now on sale, and at anchor in Milford Haven. This monster of the deep, in the construction of which the engineer has almost rivalled the mechanism of organic life, has a gross tonnage of 22,500 tons, and a nominal steam-engine power of 2,600 horses. Its cost now stands in the books of the company at 86,000*l.*, and it is said to be in excellent order. Its length between perpendiculars is 680 ft.; its length on deck, 691 ft.; its extreme breadth, 83 ft.; the depth of side, 58 ft.; and its estimated draught when laden, 30 ft. There is a close and melancholy connexion between the *Great Eastern* and Milford Haven. One of the facts that have hitherto militated against the commercial value of the great ship is that it is too large for almost any port. It is certainly too large for the Thames, as regards both convenience and safety. At Milford Haven there is room for a fleet of *Great Easterns*.

The *Great Eastern* was the last and favourite child of the gifted Isambard Kingdom Brunel. The writer of these lines had much intercourse with that great engineer on the subject of this vessel. Mr. Brunel told, in his dry way, how one or two friends called upon him and asked if he thought it possible to build a steamboat 1,000 ft. long. Mr. Brunel replied that he should not like to say how large a vessel he thought might be built, lest he should be thought wild; but that he thought it would be more prudent to try a little one of 700 ft. long to begin with. On that advice the *Great Eastern* was set in hand. It was proposed to Mr. Brunel to build the vessel at Neyland, opposite Pembroke Dock, where a deep "pill," or sheltered creek, forms a natural building-dock. The plan proposed was, to build the keel of the vessel, float it as soon as a couple of plates in height had been put together, and then build the rest afloat. The cost and risk of launching would have been thus avoided. Mr. Brunel pondered for some three weeks, and at last decided on the Thames, exclusively on the ground of the convenience of locality, as he would be able to run down daily from Westminster to see the vessel in progress, while to Milford the journey was formidable. England has had cause to regret this decision, powerful as were the arguments in its favour. It was impossible to launch the *Great Eastern* in the Thames, in the ordinary way, as she would have imbedded herself in the opposite bank of the river. Hence followed the novel and dangerous expedient of the side-way launch, attended not only by mishaps, but by enormous expense, and tending more than anything else that can be suggested to shorten the days of Mr. Brunel. That cost, that mishap, and that anxiety, would all have been avoided if the proposal to build the necessary shops and to undertake the construction of the vessel in Milford Haven had been accepted by the great engineer.

PORTRAITS OF AMERICAN PRESIDENTS.

The deplorable death of President Garfield suggests the memory of the series of portraits of the Presidents of the United States that hang in the Capitol at Washington. It is a noteworthy fact, and one, perhaps, that has not unfrequently been observed, that august personages have not always been fortunate in the manner in which they have been portrayed by painters and sculptors. Of the large number of royal persons that have existed within past centuries, it is difficult to point to many pictures or statues as perfectly faithful or trustworthy representations. Though we possess a curious and almost complete series of our English kings and queens, how many of these portraits are there that we may look upon with thorough faith? How many represent their originals, not from a preconceived and artificial conception of their appearance, but as they really lived? We feel that we may rely on Holbein's portraits of Henry VII. and of Henry VIII.; and the many representations of Queen Elizabeth concord sufficiently to enable us to form some just idea of the Virgin Queen. Van Somers has pictured us James I.,—is it, however, really the pedantic Scotchman Macaulay has so unflatteringly portrayed in one of his literary profiles? On Walker's representation of "Old Noll" we may thoroughly rely for a portrait of Cromwell. Van Dyck, though he flattered his models, has fixed for ever in our minds the Charles I. of history; Lely's powers of accuracy we doubt too much to trust to his version of Charles II.; the eighteenth century was too artificially courtly for us to place our faith in any royal portrait of that age, and it is not till we meet Reynolds that we can venture to rely on any existing portrait of George III.

The American Presidents have been no more exempt from this fate than the crowned heads of the Old World, and of the nineteen Presidents who preceded General Garfield, but one has been portrayed by a painter on whose powers as an artist and as a delineator of nature at the same time we may perfectly rely; we refer to the portrait of General Washington by Gilbert Stuart, and that portrait, curious to say, is unfinished, the head being all that is painted, the rest being what painters call "clean canvas."* Stuart was well aware of the merit of his work, and was wary enough not to complete it, using it as the original from which he copied the innumerable portraits of the founder of the American republic that were at the time distributed over the United States, and which bear Stuart's name. The painter cleverly succeeded in retaining his original portrait, which is now one of the most justly-prized of the rapidly-increasing artistic treasures of Boston. Taken late in Washington's life (in 1794), and representing him at a period when the costume of the courts of Europe was exceedingly elaborate, Washington at his request is dressed in black velvet, with the powdered wig and black "bag" of the period. The truthfulness of the resemblance, even if we had not the authority of contemporaries, would be shown by evidences in the work itself that are unmistakable to the experienced eye, so much so that the amusing story,—one we believe not generally known,—that Washington waited before sitting for his portrait until a new set of teeth arrived from Paris,—is confirmed by the peculiar expression of the mouth which the painter in his truthfulness, perhaps in his humour, made perfectly evident. A more than usual interest is attached to this portrait, not alone on the score of its historic and artistic value, but from the incidents by which both it and the painter are connected with England, and for the facts of which the still-existing traditions,† and the statements of Dunlap, —the Horace Walpole of American art,—are evidence.

It was from his unfinished portrait that Gilbert Stuart painted the large portrait for the Marquis of Lansdowne, from which was engraved at the time James Heath's superb and well-known work. Copyright laws between England and America no more existed in those "good old days" than now, and we can well understand Stuart's feelings at the success of Heath's print, though he jokingly remarked (and Stuart has left behind him the reputation of a wit), with reference to the inaccuracy of the engraver's mention of his name as "Gabriel," "Men will make an angel of me in spite of myself."

Gilbert Stuart, like most of his contemporary brother artists, crossed the Atlantic, and in the days when not a few Americans remained still good Britishers,—Stuart's father was a Scotchman,—found his way to London, and here he remained some years. To West, as might be supposed,—being, like himself, an American,—young Stuart went, and in his studio in quiet Newman-street saw most of the visitors to the favourite painter. There is a story extant that one day Dr. Johnson called on West to gather from him any information he might possess regarding America. West, who had left his native country some years, referred the Doctor to his newly-arrived pupil, young Stuart. After some conversation, Johnson patronisingly asked the witty young American who had so pleased and instructed him, where he had learned such good English; to which Stuart's prompt, if scarcely polite, reply was, that he could better tell where he did *not* learn it,—from the Doctor's Dictionary. Stuart quickly gained a name over here, and from York-buildings, where he had first lodged, he moved to a fine house in Berners-street, Oxford-street, at the very respectable rent for 1782 of 150*l.* a year.* Our National Portrait Gallery contains two portraits by Stuart, —one of Kemble, the other of his old friend and master, Benjamin West.

THE NEW EASTBOURNE AND TUNBRIDGE WELLS RAILWAY.

In the course of the last few years many important new works have been executed by the London, Brighton, and South Coast Railway Company in numerous localities embraced by the company's system. These works have included the erection of many new passenger, goods, and coal stations, and the enlargement and re-arrangement of others, and also the construction of new lines for the accommodation of the growing traffic of the company; one of these, the communication between Chichester and Midhurst, was noticed in a recent number of the *Builder*. The last completed extension of the company's system is the line between Eastbourne and Tunbridge Wells, which is now finished by the completion of the important new station and works at Polegate, near Eastbourne. Another and much larger extension than either of those referred to is rapidly approaching completion in the new lines, upwards of forty miles in all, that will provide, practically, an additional trunk line from Croydon to Lewes, Newhaven, and Hayward's Heath, *viâ* East Grinstead. These extensions in East and West Sussex, and across Surrey and Sussex, are revivals of schemes that were projected, and the works partly executed, many years ago.

Several surveys for a line to connect Eastbourne with Tunbridge Wells were made before the scheme as now carried out received Parliamentary sanction. These were promoted by the Brighton Company, by the South-Eastern Company, and by independent companies. The Surrey and Sussex was resumed after having been abandoned for a time; it was the scheme of an independent company, and was next taken up by the Brighton Company, by whom the works are being executed. East Grinstead will be a principal station on this line, being at the point of intersection of the lines from the Isle of Wight, Portsmouth, Littlehampton, Horsham, and Three Bridges on the west and south-west, and Tunbridge Wells on the east, and the new line from north to south between Croydon and Lewes. Although East Grinstead does not now return, as it once did, two members to Parliament, it is a place of considerable and growing importance. The parish, the largest in Sussex, contains 15,072 acres. It has a population of nearly 10,000, the increase during the last ten years having been 1,185.

The earliest proposals to give Tunbridge Wells the benefit of railway communication excited the hostility of the owners and occupiers of property, who feared that injury would result from

* Resembling in this treatment the well-known portrait in our National Portrait Gallery of William Wilberforce by Sir Thomas Lawrence.

† The writer in 1849 had the opportunity, in America, of frequently meeting the two daughters of Gilbert Stuart, two old ladies whose anecdotes relating to Washington and his period were as famous in America as were the recollections with us of the Misses Berry.

* Mrs. Hoppner, in a letter quoted by Dunlap in his "History of the Arts of Design in America," writes under date June 3, 1782,—"Mr. Stuart has taken a house, I am told, of 150*l.* a year rent, in Berner's-street, and is going to set up as a great man."

facilities for reaching their charming locality quickly, and at moderate cost. With experience of the influence of railways in promoting the comfort, convenience, and prosperity of the inhabitants of the districts they reached, and in increasing the value of real property, opinion changed, and owners of property who had formerly opposed local railways became their strongest supporters. The first line that reached Tunbridge Wells was made with the full consent of all parties interested, was unopposed, and was actually made without even the powers usually conferred by an Act of Parliament.

The desire for railway communication between Eastbourne and Tunbridge Wells existed long before Parliamentary powers were obtained for the construction of the line now completed. We believe that the Duke of Devonshire, to whom the great part of Eastbourne belongs, was prepared to make a line himself, if a company could not be induced to undertake it. The Brighton company took up the project, and have made the line. A portion of the route was already in their hands in the lengths from Polegate to Hailsham, at the southern end, and between Tunbridge Wells and Eridge on the north. To link together these two stations, and to provide continuous communication between Eastbourne and Tunbridge Wells, about 16¾ miles of new line were needed, and have been provided.

On the new portion of the line there are five stations. Polegate and Hailsham had already their stations; at Polegate a new and admirably appointed station has been provided, and the buildings that have hitherto served for the accommodation of the passenger traffic will be converted into a goods station, or put to other uses.

Before referring more particularly to the new line, it may be admissible to state a few facts concerning its termini. The older parts of Eastbourne,—Meads, Southbourne, and Seahouses,—are of great antiquity, their historic traditions, dating much further back than the time when William the Norman and his host landed in Pevensey Bay, close by, before the battle of Hastings. The locality was the site of a Roman settlement, and many interesting Roman remains have been found near the coast at that place. Eastbourne is, however, a comparatively modern creation as a favourite watering-place, and now one of the finest on the coasts of the United Kingdom. Its well-merited popularity may be attributed to a combination of causes, —the grandeur of the coast, the breezy downs, pleasant walks, pure air, mild climate, excellent sea-bathing, efficient sanitary provisions, the number and superior character of its hotels and residences, and last, but not least, the munificence and taste exercised by the Duke of Devonshire in effecting public improvements. In 1801 the population of Eastbourne was 1,668, in 1821 it was 2 607, in 1851 it was 3 403, in 1881 it has reached to 24,333, with 3,821 inhabited houses, the increase in ten years having been 11,356 in population, and 1,573 in inhabited houses; its area is 19,145 statute acres.

Tunbridge Wells, at the northern end of the new line, has had the start of Eastbourne as a fashionable place of resort for those who seek after health and pleasure. It is, excepting Bath, perhaps, the oldest and most charming inland watering-place in the kingdom. So long ago as 1606, it is chronicled, Dudley, Lord North, accidentally discovered the medicinal virtues of the chalybeate springs at Tunbridge, which led to the fame of the place, but its remarkable growth has been since the commencement of the railway era. For long after the days of Lord North, the Wells were treated as an appendage of Tunbridge, and the statistics of the one place were included with those of the other. It may suffice, to show that Tunbridge Wells, like Eastbourne, is a place that grows rapidly, to state that in 1861 its population was 13,807, and in 1881 was 30,352, or considerably more than double. The increase in population in the twenty years has been 16,545; in inhabited houses, called 5,733 by the census of 1881, the increase has been 2,240. The population of Tunbridge town at the last census was only 14,687, or less than half that of Tunbridge Wells.

Eastbourne and Tunbridge Wells have in common a beautiful feature in the interspersion of fine greenery with the buildings; the rows of flourishing trees in the streets and roads of Eastbourne, and the preponderance of private dwellings and residences of professional men and gentry over ordinary places of business, are remarkable. Tunbridge Wells abounds in rich and varied beauties peculiar to itself and the district in which it is situated, notably in its fine commons and picturesque rocks.

Leaving Eastbourne by rail, and looking back upon it, a pretty view is obtained of a considerable part of the town, and of the tops of the long range of Martello towers that stud the coast. Eastward, in the direction of Hastings, an extensive plain affords excellent pasturage for the live stock of various kinds that are so plentifully sprinkled over it. This large area includes the Willingdon and Pevensey levels. Polegate Junction is reached at a few miles' distance from Eastbourne.

The through Brighton lines between east and west pass between long platforms at the station. There are four of these platforms, each 600 ft. long by 30 ft. wide, and for the greater part covered with elegant roofs of glass and iron. The station buildings are an imposing pile. Red and white brickwork does not resist the influence of saline breezes, which discolour and disintegrate frontages built in such material; the Polegate Station buildings are accordingly faced in cement, and the style adopted is Italian. The other station buildings on the new line are Old English, with fronts of red and white brick, the dressings and mullions of the windows being of Portland stone. The roofs of the Polegate Station buildings are covered with slates; those of the other stations with flat red tiles, and finished with terra-cotta finials and ridges. On the ground-floor at the Polegate Station the principal block of building has suitable conveniences at the extreme end of the building; then follow a cloak-room, 15 ft. square; passage for luggage; ticket and telegraph office, 15 ft. by 16 ft.; booking-office, 30 ft. by 16 ft.; waiting-room, 16 ft. by 12 ft.; a ladies' room, lobby, and at the extreme end again, station and house coal-stores. On the platform level, 14 ft. higher than the ground-floor, there are lobby, closets, &c.; ladies' room, 16 ft. by 11 ft.; general waiting-room, 20 ft. by 16 ft.; refreshment-room, 24 ft. 6 in. by 16 ft.; and a kitchen, 16 ft. by 9 ft. There are also provided a station-master's room, 15 ft. by 11 ft.; and a ticket-collectors' room, 13 ft. 6 in. by 11 ft. The station-masters' residence, on the first floor of the station buildings, includes a sitting-room, 18 ft. by 12 ft.; kitchen, 12 ft. square; with three bedrooms of about 12 ft. square each. Station-master's family accommodation is provided at all the stations. The subway for communication between the platforms at Polegate station seems a good piece of work. It is 150 ft. long, 10 ft. wide, and 8 ft. 6 in. high, lined with white enamelled bricks, and well lighted with Hayward's patent lights. There is communication by a double flight of steps between the subway and the central platform, and by single flights with each of side platforms. Provision on a liberal scale is made, or is in progress, for the accommodation of goods, mineral, and cattle traffic. Goods and mineral traffic are provided for at all the stations on the new line, which commences at the thriving market town of Hailsham, population 6,702.

A railway line nearly seventeen miles in length, traversing an undulating country, crossing many roads and streamlets, and that has occupied four years in construction, which is about the time since Mr. Joseph Firbank, the contractor, commenced operations, implies much hard work and clever contrivance, displacement of material in some places, and deposit of material in others. There are fifty distinct cuttings and forty-nine embankments on the line, and seventy-four bridges and culverts. The line crosses the Redmill stream nine times, and also crosses the River Cuckmere, and many smaller streamlets. The summit of the line is near Heathfield, about eight miles from Hailsham, or nearly half-way. It is 384 ft. higher than the level of the line at Horsebridge, the lowest point. The gradients and curves are for the most part easy, and all perfectly practicable. The contour of the country is partly indicated by the fact that on each side from the summit there are rising and falling gradients, and reaches of level. The bridges over and under, culverts, and other engineering works, are not of a character to call for special remark. The station works at Polegate, Mayfield, and other places have a stronger claim for notice. The first new station on the line after leaving Hailsham is at Hellingly, a pretty country town and parish of about 6,700 inhabitants. As may have been already inferred, there is just about the same proportion of the line on embankment as there is in cutting. In almost every instance of the open being reached, beautifully picturesque scenery, sometimes in extensive reaches, presents itself, charming in its variety and gradations of light, shade, and colour. The country is well wooded, but has also many hop-gardens, meadows, and fields under cultivation between the clumps of plantation. Game of various kinds is abundant, good for huntsmen as well as "hoppers," who do not, of course, follow their distinctive pursuits simultaneously.

Horeham-road is the next station. The scenery near this station is very fine, and includes a beautiful view across the valley of the river Cuckmere, which reaches the Channel at Seaford. At Heathfield, and near it, there have been some very heavy works in cuttings and in embankments, and in a tunnel of about eleven chains, cut through very hard rock. Some of the embankments, containing immense masses of earthwork, gave much trouble hereabouts, from spreading out at the base. They seem now thoroughly consolidated. Heathfield Park, near the station, now in the occupation of Lord Claud Hamilton, M.P., was at one time the residence of Lord Heathfield, of Gibraltar renown. When Sussex was celebrated for the iron produced in the county, Heathfield was famous as a cannon foundry. It has one of the largest corn-markets in Sussex.

Mayfield, seen from the line, presents a very pretty picture. The scenery around is very charming, and a succession of fine views is commanded from the line. The archiepiscopal palace is a well-known relic of architectural and antiquarian interest. It was the favourite residence of the Archbishops of Canterbury from the time of St. Dunstan to Cranmer. In 1573, seventeen years after Cranmer's martyrdom, Mayfield Palace was in the occupation of Sir Thomas Gresham, of the famous London citizen and founder of the Royal Exchange, and he in that year fêted Queen Elizabeth at the Palace. It was purchased in 1863 by the Duchess of Leeds, and converted into a convent, under the architectural direction of Mr. Pugin. The fine banqueting-hall is used as the convent chapel. The Mayfield district has many attractions for naturalists as well as antiquaries. We notice that the Brighton and Sussex Natural History Society had a field excursion to Mayfield on the 10th ult. The Mayfield Station is the largest on the new line, excepting Polegate, which is entirely different in external appearance and internal arrangements. The other stations are similar to that at Mayfield, in general appearance and internal arrangements, only somewhat smaller, and have not some of its adornments in the shape of lead-fret glazing and tinted glass.

Rotherfield, from the river Rother, that for part of its course is the boundary between Sussex and Kent, is the last station on the new line, although not the end of the route. In this neighbourhood the line skirts the shoulder of Argus Hill, an eminence of considerable height upon a terrace. Near here also is Crowborough Lodge, the seat of Mr. C. L. Prince. Crowborough Beacon is an eminence 804 ft. high, upon the summit of which is an astronomical observatory.

The line from Lewes joins the new route before entering Eridge station. At a short distance beyond the station a newly-made curve strikes off to the left for Withyham to join there the line from Tunbridge Wells to East Grinstead and numerous other places and junctions; the other curve, to the right, continues the line past Groombridge station to Tunbridge Wells,—the end of the journey.

It is not too much to say that the new line passes continuously through a country that presents a marvellous assemblage of the beauties of nature; among hills and vales, woods and brooks, lawns and rocks and groves, orchards and hop-gardens, scenes that are here "wildly noble," and there,—

> "By shallow rivers, to whose falls,
> Melodious birds sing madrigals."

The principal landowners through whose property the line passes are the Marquis of Abergavenny, Mr. H. Dalby Hunt, representatives of the late Mr. F. A. Schroeder, Mr. W. Tooth, Sir Charles Wm. Blunt, bart., &c.

The line was laid out by Mr. F. D. Banister, engineer-in-chief of the Brighton Company; contractor Mr. Joseph Firbank; signals are by Messrs. Saxby & Farmer; designs for stations by Mr. Myers, of Westminster; station works by Mr. Longley, of East Grinstead. The resident engineer is Mr. S. Paine; contractor's superintendent, Mr. Throsall.

The new line is single, except at stations, where accommodation for traffic in sidings is provided. The slopes of cuttings and embankments are 1½ to 1.

REVIEW OF THE HALF-YEARLY MEETINGS OF THE RAILWAY COMPANIES.

THE METROPOLITAN RE-ASSESSMENT AND THE SURVEYORS.—INTERESTING STATISTICS.—LARGE OUTLAY ON NEW LINES.

THE reports presented at the half-yearly meetings of the several railway companies which have just been held will in many respects be found to be of a specially interesting character. As regards several of the great lines having termini in the metropolis, the invidious position of the surveyors and valuers under the recent re-assessment of property in London formed a prominent subject of discussion and complaint. At the meeting of the *Great Eastern Company*, the chairman, adverting to the question, said that the magistrates themselves had denounced the system of employing gentlemen as valuers and surveyors who were paid by a percentage on the amount of their assessments. In proof of this the chairman quoted the remarks of Mr. Edlin, the Assistant Judge, on a recent appeal at the Middlesex Sessions. On that occasion Mr. Edlin observed that "it was elicited from an eminent surveyor and valuer that, being employed by the overseers, his remuneration depended on the increased amount in the assessment of the rateable value of the property of the parish, as compared with the last valuation list. It was the unanimous opinion of the court that they could not too strongly reprobate such a system of payment. It was calculated to destroy the value of testimony offered in court, and to shake their confidence in any figures brought before them, besides creating dissatisfaction and annoyance in the minds of all ratepayers whose valuations were increased. The only object of parish officers and assessment committees should be to put a just and reasonable valuation upon the property within their district, and any valuation which gave a personal pecuniary interest to the valuer must necessarily be open to grave suspicion." The chairman of the *North London Company* also drew the attention of the shareholders to Mr. Edlin's observations from the bench. The chairman, in continuation, said he admitted that these surveyors ought to be paid handsomely, as they were gentlemen of education and experience, and had a position in society, and he was not desirous of depreciating them or derogating from their services, but what he insisted upon was that if they paid such a body of men on the principle of receiving 5 per cent. on the increased value of the assessment, it was an inducement for them to do what was not quite correct. The subject was likewise alluded to by the chairman of the *Midland Company*, who observed that in the parish of St. Pancras, as they were all aware, the company had a very valuable property, which had been assessed for the last five years at the annual value of 53,700*l*. At the late re-assessment the parish engaged the services of a competent rating surveyor, on the terms of 5 per cent. commission on the increased rateable value he obtained, and acting on his valuation they claimed an assessment of 79,000*l*. The directors, thinking that some increase ought to be made, and anxious to avoid litigation, offered to settle an assessment of 60,000*l*., but this was declined, and the Assessment Committee, when appealed to, supported their own surveyor. The case was ultimately referred to Mr. Pownall, an arbitrator of very large experience, who reported to the Court of Assessment Sessions that the fair rateable value was 58,289*l*., which the Court confirmed, awarding to the Midland Company the costs of the appeal and arbitration.

From the general proceedings at the meeting of the *Midland Company*, it appeared that during the half-year there had been an increase in coaching traffic of 15,955*l*., and from minerals 74,690*l*., and a decrease in merchandise traffic of 37,996*l*, and in cattle 6,110*l*., the net increase being 46,539*l*. The number of first-class passengers carried had been 954,323, or 15,138 less than last year, and the number of third-class passengers 11,818,749, or 214,341 more than last year. The total capital expenditure during the half-year on lines open for traffic and on lines and works in course of construction had been 702,822*l*., and the estimated capital expenditure for the current half-year was 950,000*l*., and for future half-years 3,734,784*l*. As to the Poplar goods station and dock, it was stated that the river-wall and dock are now finished, and that the gates being completed, the water can be let into the dock, and the coffer-dam removed. The sidings were being laid for the yard and branch. The large warehouse was built up to the second-floor level, and the smaller one up to the first floor. Buildings for the hydraulic machinery had likewise been commenced. The works at the Tottenham and Hampstead north curve had been commenced, and the retaining-wall of the junction with the main line, together with the covered ways, and the cutting near the Brecknock-road, were in progress. It was stated at the meeting that the growth of the traffic in and out of London had rendered essential a second tunnel between Haverstock-hill and Finchley-road. A contract was entered into in March last for the construction of the tunnel. The works had been commenced, and the shafts were all in a forward state, which would enable the contractors to proceed with the tunnel immediately. In the course of the meeting the chairman alluded to the question of brakes, the introduction of which is now being insisted upon by the Board of Trade. He stated that the company had at present 57 engines and 209 vehicles fitted with the Westinghouse automatic air-pressure brake appliances; 202 engines and 2,074 vehicles fitted with the Saunders and Bolitho automatic vacuum brake appliances, of which 80 engines and 809 vehicles were fitted in the last half-year. They had likewise 26 engines and 115 vehicles fitted with Smith's vacuum brake, and they had 2 engines and 11 vehicles fitted with Barker's brake.

The report of the *Great Western Company* stated that there was an increase in the traffic receipts as compared with those of the corresponding half-year of 1880, of 49,042*l*., passenger traffic, merchandise, and minerals having all partaken of the increase. The dividend declared was at the rate of 4½ per cent. per annum. The progress of the Severn Tunnel formed a prominent feature in the report, which stated that during the past five months about 270 ft. of the permanent tunnel under the Severn had been completed, and a total length of 530 ft. of the arch of the tunnel had been formed under that part of the river known as the Salmon Pool, to the westward of the sea-wall shaft. In answer to a question by Sir Charles Whetham as to whether they were tunnelling under the land or the water, the chairman replied that they had tunnelled under the most difficult part of the water, and that a most difficult part was accomplished, which was called the Salmon Pool, on the English side of the Severn. The tunnel was roofed in there and completed, and it was the only portion where they really had any anxiety. At the meeting a vote of 60,000*l*. was granted for the following works now in progress:—Doubling the Wilts, Somerset, and Weymouth line between Waltham and Maiden Newton, 14,000*l*.; new offices at Paddington and enlargement of the station, 20,000*l*.; Plymouth Docks, additional accommodation, 8,000*l*.; Swansea East Dock coal-tips, 15,000*l*.; and new passenger station at Tilehurst, 3,000*l*.

The *Great Northern Company's* report showed that the gross traffic receipts of the company during the half-year amounted to 1,541,179*l*., as compared with 1,514,465*l*. in the corresponding period of 1880. The traffic for the half-year, the report observed, had been well sustained, though during the serious interruption caused by the severe winter, in January and February last, there was a large falling off in the receipts, and at the same time a considerable increase in the working cost. In the course of his remarks at the meeting, the chairman drew attention to the continued decrease in the number of first-class passengers, and the increase of third-class passengers, observing that there had been a decrease in the first-class of 6,187 in numbers, and a decrease in money of 6,172*l*. There had been an increase in the second-class of 49,402 passengers, but a decrease in money of 4,227*l*., which was accounted for by the short distances. The majority of the second-class passengers had travelled in the suburban districts, where the distances were very short and the fares very small. There had been an increase in the third-class of 442,945 passengers, and an increase in money of 5,905*l*. The percentage of first-class passengers was on the whole decreasing, and was now only 4½ per cent. The second-class was stationary, and remained at 10 per cent. The third-class was still increasing, and now amounted to 85½ per cent. The capital expenditure on lines open, and on new lines and works, during the half-year, had been 540,011*l*.; and 77,211*l*. was required to be expended during the current half-year in additional works for the accommodation of the traffic. The most important items were new platforms, sidings, and stables, the London goods station, and the extension of the passenger station at Nottingham. The accident at the Sutton Bridge Docks, in which the company is largely interested, was referred to by the chairman, who said it was a great disappointment to the directors that the catastrophe had occurred. The docks were hardly finished, and vessels had only just begun to enter the basins and discharge their cargoes or export coal, when the calamity occurred, which they must attribute to the treacherous nature of the soil of the place. A leakage took place under the locks and led to the damage which took place. The company had subscribed 55,000*l*. towards the undertaking, and they had two of the Board representing the company on the Dock Board. They had hardly made up their minds what was to be done regarding the docks. They had a report from several eminent engineers, and they knew pretty well what they recommended, but to carry out their recommendations would entail considerable expense, and at that moment the dock company had no money to expend. On the motion of the chairman, the railway company were empowered to take such steps as they might consider necessary to secure the company's interest in connexion with the docks, and to expend any sum that might be deemed requisite to protect the docks from further injury.

In the *Builder* lately (p. 290, *ante*), the proceedings at the meeting of the *London and North-Western* Company, relating to railway taxation, the falling off in the Irish traffic, the Employers' Liability Act, and some other matters, were noticed. The chairman, in his speech moving the adoption of the report, made some interesting remarks on the new works which had for some time past been in progress on various parts of the company's system, and also drew the attention of the shareholders to the additional expenditure which it is proposed to incur on further new lines and other works. Adverting to the former, he said that the London-road Station at Manchester was now very greatly enlarged, as well as the Lime-street Station at Liverpool. If any one, he observed, would go to Manchester, he would say that the wonder was that they could have gone on with the former station at all. But it was now different. They had also opened for goods the duplicate station at Northampton; and by January he hoped Northampton would have its passenger-station ready, and thus bring in the North-Western line. He did not believe it was the intention of Stephenson to go through Northampton; there was a tradition, too, that the people of Northampton objected to it. He could not have got the line with the present gradients. They had now other advantages by the new line which would go through Northampton. They had put that line on the old main line through Rugby, and on the new main line to Nottingham and the North. The company had now a double line all the way from London to Birmingham, a double road to Northampton, a double road to Crewe, and through to Liverpool, and with the assistance of the North Staffordshire Company, they had two roads to Manchester, and two to Chester, and shorter than any one else. The directors were authorised to expend, in conjunction with the Midland Company, the sum of 820,630*l*. on new lines, including the Market Harborough line; and also 50,000*l*. in the construction of additional lines and sorting sidings at Edge Hill, Liverpool; 35,000*l*. for sidings and improvements at Patricroft, Manchester; 22,000*l*. for sidings at Wolverton; 83,283*l*. for additional sidings and other accommodation; 114,756*l*. for additional land and minerals; 50,000*l*. for additional rolling stock; and 65,000*l*. under the Watford and Rickmansworth Railway Transfer Act,—total, 305,039*l*., being an aggregate expenditure (including the joint expenditure with the Midland Company) of 1,125,669*l*.

The *Great Eastern Company's* report stated that the accounts showed a gross revenue from all sources of 1,424,291*l*., against a gross revenue of 1,398,079*l*. in the corresponding half-year of 1880. The passenger and goods traffic had suffered from the closing of the cattle markets; whilst the severe winter and heavy falls of snow occasioned a considerable increase in the expenditure of the various departments, the

working expenses showing a gross increase of 20,762*l.* Satisfactory progress had been made with the works on the Northern Extension, and the directors hoped that the portion from Spalding to Sleaford would be opened during the present year. Adverting to the enlargement of the Fenchurch-street Station, the chairman said he hoped it would be completed before this time next year. They would then be enabled to get in and out a greater number of trains, and to further accommodate the suburban districts which they supplied. He added that they were about to widen the line from Stratford very nearly to Bethnal-green, by making four lines of rails.

At the meeting of the *London and South-Western Company* the chairman stated that the company had suffered from the great snow-storm and the severe winter, which was felt more severely in the southern and western districts than in the east and north. The severe winter had cost the company 31,000*l.*, and if the directors had had that amount of money to dispose of they would have been able to carry over the same balance as they did in the corresponding period, and to pay the same dividend. There had been a decrease in the revenue during the half-year of 3,025*l.*, and an increase of 28,823*l.* in the expenditure. The dividend declared was at the rate of 4¾ per cent. It was stated that the widening of the line between Clapham Junction and Surbiton would probably be finished in the course of the year, and the line from Surbiton to Hampton Court Junction would take about two years. The new line between Surbiton and Guildford would be shortly commenced. The chairman stated that the important subject of extending the line from Waterloo into the City was receiving careful consideration by the directors, who were making all necessary inquiries with a view to the decision of the question in the interests of the shareholders.

The report of the *London, Chatham, and Dover Company* stated that the gross receipts for the half-year amounted to 530,156*l.*, as compared with 523,583*l.* for the corresponding period of 1880, being an increase of 6,574*l.* The report also stated that the Board proposed to proceed as rapidly as possible with the several new works authorised by the Act of the late session. They include the new bridge over the Thames and the station opposite the *Times* office; the Maidstone and Faversham Junction Railway; a junction to connect the Dover and Deal line with the main line; and two extensions at Greenwich and Sheerness. The works are to be proceeded with in the order of their urgency, the extension at Blackfriars and bridge across the Thames being the first.

At the meeting of the *South-Eastern Company* the chairman stated that the results of the traffic during the half-year had not been satisfactory to his mind. They had received practically 16,295*l.* more money from one source or another, and managed to spend 20,630*l.* to get it. He found that during the last desperate winter they spent 2,168*l.* in clearing away the snow, and they sustained a loss of nearly 10,000*l.* in traffic. As regards the company's new works, it was stated that the West Wickham and Hayes and Hundred of Hoo lines, including the deep-water harbour on the Medway, were making satisfactory progress; the contract for the Woodside and Croydon line had been taken by Mr. Joseph Firbank; and the extension of the North Kent line from Strood to Chatham and the construction of a line from Northfleet to Snodland would shortly be commenced. The chairman announced that the Charing-cross Hotel had now been fully purchased from the hotel company by the railway company.

The report of the *London, Brighton, and South Coast Company* stated that the receipts from traffic for the half-year amounted to 931,222*l.*, as compared with 927,085*l.* in the corresponding period of 1880, showing an increase of 4,137*l.* The Tunbridge Wells and Eastbourne, the Ryde Pier and Railway, and the Chichester and Midhurst lines, had just been opened, and progress was being made with the Lewis and East Grinstead line, the Croxten and Oxted line, and the Newhaven Harbour. Regarding the last-named undertaking the chairman remarked that no doubt they were throwing their bread upon the waters in the hope that it might come back to them another day, and he believed it would. He looked forward to the time when the deep-sea harbour at Newhaven would give them a great deal of continental traffic in different directions.

The traffic receipts on the *North-Eastern line* for the half-year amounted to 3,079,161*l.*, as against 3,115,965*l.* last year, being a slight decrease, but admitting, after expenditure, of a dividend on North Eastern Consols and the New Stock at the rate of 7½ per cent. per annum. Referring to the traffic in the different classes of carriages, the chairman said that they carried 415,000 first-class passengers, as against 453,000 in 1880. The second-class passenger traffic also showed a continuous decrease. In the last half-year they carried 529,000, against 600,000 in 1880, and 643,000 in 1879. But the third-class traffic continued to increase. There was a steady and regular augmentation of third-class passengers, of whom they carried in the past half-year 12,756,000, as compared with 12,193,000 in 1880, the increase being 563,000, and an increase of no less than a million and a half over 1879. That showed that there was a tendency to travel in a cheaper class of carriage, and, therefore, they had made a considerable reduction in both first and second class fares. They were largely converting first-class into third-class carriages.

The proceedings at the meetings of the *Metropolitan* and *Metropolitan District Companies* were chiefly interesting so far as they referred to the prospect of the early completion of the Inner Circle.

The report of the *North London Company* stated that, notwithstanding the interference with the traffic arising out of the severe weather in the months of January and February last, the receipts of the last half-year showed an increase from all sources of traffic, admitting of a dividend at the rate of 7½ per cent. per annum on the ordinary stock.

The *Lancashire and Yorkshire Company's* report showed the traffic receipts for the half-year to be 1,741,841*l.*, against 1,717,700*l.* in 1880, and a dividend at the rate of 4¼ per cent. per annum was recommended. The amount of capital expended during the half-year was 306,353*l.* and 290,735*l.* would be required for expenditure on new works during the current half-year. The property required for the new Exchange Station in Liverpool had, for the most part, been obtained, and the work would before long be commenced.

It appeared from the proceedings at the meeting of the *North Staffordshire Company* that the line suffered greatly during the winter time from floods. The chairman stated that the Churnet ran down a part of their railway, the Dove ran down another part of the line, and the Trent also ran down another part; so that they were subject to floods from three different sources. These floods were very disastrous, and washed away the ballast on their line, and injured their bridges, rendering necessary a large expenditure in repairs and other works.

A BRIEF CHRONICLE OF NEWGATE.

The prison of Newgate is doomed. Probably before the present year draws to a close the work of its destruction will be commenced.

"B. L., of Twickenham," in "An Accurate Description of Newgate" (London, 1724), writes:—"Newgate, the county gaol of Middlesex, is situated in an elegant part of the west of the city of London, called Newgate-street. This prison was built either in the time of Henry I. or that of King Stephen, but in which there is no certainty; and was then (as it has ever since continued to be) a prison for debtors, felons, &c. About 300 years after the first founding of the prison, it became terribly loathsome; and, therefore, was in the year 1412, rebuilt by the executors of Sir Richard Whittington, in the reign of Henry VI. The architecture of this structure is of the Tuscan order, magnificently built with stone, with great strength and beauty." It was repaired in 1630, and in 1672, after being nearly destroyed in the Great Fire. It received its name from the circumstance of the rooms in the postern over the new or latest built gate of the city being used for the detention of prisoners. In "A History of the Press Yard" (London, 1717), which was one of the three divisions of the prison, the author, who was incarcerated along with certain of the Scottish Rebels in 1715–16, writes:—"This tomb of the living (the Press-yard) was once the Phœnix Inn, by Newgate-street, and being contiguous to the gaol of that name, and very convenient for enlarging the territories of one of its keepers, of tyrannical memory, was added to it in the times of the Usurpation." The gaol was burnt by the rioters in 1780, before the completion of the present building, which was designed by Dance, the architect of the Mansion House, and finished in 1783.

The walls of Newgate during the last 600 years have inclosed a motley multitude of prisoners, famous and infamous. In 1241 several rich Jews were ordered to pay 20,000 marks or to be kept perpetual prisoners in Newgate, and shortly afterwards King Henry sent the sheriffs to the Tower, and fined the City 3,000 marks, for allowing a priest who had killed a prior, a cousin of the queen, to escape from Newgate. In 1457, Lord Egremond, Sir Thomas Percy, and Sir Richard Percy, were committed to Newgate for a fray in the north country with the Earl of Salisbury's sons. The cells of Newgate opened their doors to many of the Puritans. At the Restoration, George Wither, poet and pamphleteer, and George Sackville, poet, *roué*, and Earl of Dorset, occupied cells in Newgate. William Penn, the founder of Pennsylvania, was committed to Newgate for six months for street preaching in 1622; and, in 1703, Daniel Defoe, for having written his treatise "The Shortest Way with Dissenters," was fined, pilloried, and committed to Newgate. It is not necessary to make any selection from the list of criminal offenders of the Jack Sheppard and Jonathan Wild, the Greenacre and Daniel Good class, for mention here.

Geoffrey Chaucer, the poet, is said at one time of his City life to have resided in Newgate, but not as a prisoner. In a black-letter pamphlet entitled "The Discovery of a London Monster, called the Black Dog of Newgate, imprinted at London by G. Eld for Robert Wilson, and to be sold at his shoppe at the new gate of Graye's Inne, 1612," is a representation of one side of the postern of Newgate, a tower with a grated door leading to grated chambers above, from one of which a disconsolate prisoner is gazing through the bars. This rough cut agrees in the main with some of the oldest extant representations of the ancient gate, the "fifth principal," as Stow terms it, in the City wall.

ROADS AND RUIN.

The road question in London is becoming very serious,—more serious than it ever has been. The adoption at one time of Macadam, then of asphalte, and now of wood, and the failure of all in certain instances, have led, and are leading, to constant stoppages of traffic and dire mischief to individuals living in the line of operations. The rapidity with which roads now get out of order is very striking, and the increased length of time during which the traffic is turned in order to do the work is equally obvious. A portion of Piccadilly, for example, between Duke-street and Regent-street, has been blocked up for many weeks, to the inconvenience and great loss of some of the shopkeepers,—a loss, in one case, we are told, likely even to prove disastrous. In other parts of the town we hear of the greatest indifference being shown to the complaints of parties inconvenienced and injured, and that twice the time has been occupied over a work that it should have needed. In the Fulham-road there seems to have been great delay, and one end of Brompton-crescent opening into it has been turned into a stone-yard or depôt for materials for an unnecessarily long period of time. We have in our eye the case of a physician there, to whose house no carriage has been able to approach for many weeks, notwithstanding repeated requests that materials placed there should be removed. We should be surprised, were he to bring an action against Messrs. Nowell & Robson, the contractors for the work, and show the positive injury that has been done, if he did not recover substantial damages.

Under the best arrangements individuals must suffer during the stoppages now so constantly taking place in the highways. It should be the bounden duty of the parish authorities and contractors to minimise this evil to the utmost.

Lightning.—The church of South Wootton, near Lynn, has been struck by lightning. The damage done is serious. The electric fluid struck the tower, splitting it almost in two, and leaving it uncertain whether one portion will not fall and so bring down the rest with it. Then, running along the lead ridge for some dozen yards, it entered through the roof into the nave, where it spread havoc in all directions. Was the church protected by a conductor?

THE "GRESHAM PRESS" NEW BUILDINGS.

The spacious plot of land, bounded on the west by the London, Chatham, and Dover Railway station, in New Bridge-street, and on the north by the buildings on the south side of Ludgate-hill, has recently come into the possession of Messrs. Unwin Brothers, and upon a portion of it they have just erected an extensive printing factory, which will shortly be ready for occupation. The principal elevation is on the north side, fronting the narrow thoroughfare known as Little Bridge-street, which runs in an eastward direction from New Bridge-street through a corner passage or neck not more than from 3 ft. to 4 ft. in width, and thence, intersecting Broadway, is continued along Pilgrim-street and into Ludgate-hill. The Corporation having secured about 10 ft. in width of the land in front of the new buildings, the Little Bridge-street frontage has been set back to that extent, which admits of the present narrow roadway being correspondingly widened. The intention of the Corporation is to open out an uninterrupted thoroughfare for vehicles into Ludgate-hill by way of Pilgrim-street.

The site upon which the new buildings have been erected has an area of about 9,200 superficial feet. The Little Bridge-street frontage, and also that in Railway-street, on the west side, facing the east side or rear of the railway station, are each 90 ft. in length, and 80 ft. in height, the chimney-shaft being carried to a height of 90 ft. In addition to a deep basement and ground floor, the building has four lofty stories. The ground-floor frontage facing Little Bridge-street consists of shops, which the owners intend to let for general business purposes, in anticipation of the opening out of the new thoroughfare already referred to. The shop frontages are carried up with Bath stone columns and pilasters, surmounted by carved capitals. The upper stories are in stock brick, with red brick for dressings and ornamentation in the Queen Anne style. The east end of the frontage is surmounted by a large gable. One of the most ornamental features of the building is the angular elevation at the corner of Little Bridge-street and Railway-street, where is the principal entrance to the premises. The whole of the lower part of this elevation is in stone, with arched entrance flanked on each side with piers and columns in Portland stone. Immediately above the doorway is an oriel window in five divisions, with carving at the base, and the inscription in prominent characters, "Gresham Press." In the centre of the building, enclosed by the respective frontages, there is a large open area for the purpose of affording additional light to the rooms and apartments on the several floors, and also for lighting the basement in which the machinery will be placed. The walls of this open area, as well as the walls of the basement, are faced with white glazed brick, and the basement is covered in with a flat glass roof or skylight, 40 ft. by 20 ft. At the top of the building there is a water-tank, capable of containing 5,000 gallons.

Mr. Rowland Plumbe, of Fitzroy-square, is the architect, and Messrs. Ashby Brothers are the contractors.

FROM GERMANY.

In celebration of the fiftieth anniversary of the Saxon Constitution, the Albrechtsburg at Meissen has been restored, with a due regard to its historic position as one of the ancestral castles of the present royal family. The work of decoration began in 1874, and in the previous year the Chamber of Deputies had voted 25,000*l.* for the restoration. The subjects of the decorations are for the most part taken from the early history of Saxony, and are in part illustrative of the building of the castle in 930. The edifice has two vaulted stories underground, and three above ground. The attention of the decorative artists has mainly been given to the first and second floors, but the third has also been suitably treated, and the ground-floor has been arranged for habitation. The armoury (which is a richly-designed piece of architecture) has been ornamented with representations of seven of the oldest Saxon and Thuringian castles. The tower, and some subsidiary buildings connected with the castle, have likewise been restored. The statue of Albrecht (the founder), cast in bronze, forms a prominent object of interest. The building was open to public inspection during the work, and last year was visited by more than 20,000 persons. A costume festival will shortly be given in the castle by a number of artistic inhabitants of Dresden.

The municipal chamber at Hamburg has lately received an important addition to its artistic ornament, in the shape of stained-glass windows, the execution of which (by local artists) seems to have given much satisfaction. The subjects represented are connected with the development of the freedom of Hamburg. The solemn and subdued effect produced by the stained glass is much approved by the press.

A vessel, described as the largest yet built in Germany for the mercantile navy, has just been launched at Kiel. It is a screw-steamer, 315 ft. in length and 37 ft. 9 in. in breadth, with a carrying capacity of 3,300 tons, and with accommodation for over 700 passengers. It has been named the *Cassius*, and will, as soon as the machinery is completed, be put on the New York line.

The *Baugewerbe Zeitung* of Berlin calls attention to the fact that speculation has brought building sites in that city to such a range of values that it is impossible to reckon upon a clear four per cent. interest for the builders, even if the cheapest materials and labour are used. It recommends caution to all employed in the selection of building sites; predicting that this movement will before long be followed by a reaction, which will remedy the exceptionally disadvantageous circumstances referred to.

A deputation from the marble industry of Cologne has waited on the German Government with a view to soliciting the abrogation of the import duty (equal to 1s. 6d. per cwt.) on sawn marble slabs, which is now being levied. The trade is not so much opposed to the imposition of the duty in itself, but to its unequal working, as the duty on marble goods, being about the same, an important development of imports has taken place, to the detriment of native industry. The Government lately asked for the opinion of some members of the marble trade, but the authorities are accused of having addressed themselves only to persons known to be in favour of the new tariff.

The Municipal Lighting Committee of Berlin has called attention to the comparatively-limited consumption of gas in that city, which the report attributes to the continued unfavourable position of business in general. The increased use of petroleum is said also to have contributed to this result; and as many as 11,000 gas communications are said to be unused at present, which would represent about one-fifth of the communications for dwelling-houses in Berlin.

THE OPEN AREA OF THE ROYAL EXCHANGE.

Our attention has been called by several correspondents to a design for covering in the Merchants' Area of the Royal Exchange, now being exhibited in the Area, of course with the sanction of the Gresham Committee. We do not know exactly the position of affairs, but we cannot avoid expressing an earnest hope that no intention exists to carry out this design. It is wonderfully ugly, unsuitable, oppressive, and altogether objectionable.

Some time ago the committee invited designs for effecting this object, and the first premium was then given to a design by Mr. F. Sang. We happen to have a small photograph of this before us, and have no hesitation in saying that it is immeasurably superior in appearance to the design now placed before the public. It is to be hoped that watchful eyes will be kept upon the matter.

Bedstone.—The workmen, 130 in number, employed by Messrs. W. Cubitt & Co. in the erection of the new mansion at Bedstone, for Sir H. W. Ripley, bart., have been entertained by him at a substantial dinner, Mr. W. C. Carter, the managing foreman, in the chair, and Mr. Marton in the vice-chair. It was stated in the course of the proceedings that the founder of the feast (who was present) had for the past twenty-five years spent from 25,000*l.* to 30,000*l.* annually in buildings. Mr. Old, the clerk of works, responded to the toast of "The Architect" (Mr. Harris), and proposed health and prosperity to the firm of Cubitt & Co., saying that if all contractors did their work as well as Messrs. Cubitt, there would be less vigilance necessary on the part of clerks of works.

ENGLISH RESIDENCE, ARCACHON, FRANCE.

A HOUSE ON THE SAND.

Arcachon, as many of our readers know, is a small town in the pine forest thirty-five miles south-west of Bordeaux, on a little inland sea called the "Bassin d'Arcachon," an offshoot of the Bay of Biscay, where a great many English reside during the winter months. This is the first English villa erected there, and is built on the sand in the midst of the pine-trees which extend from Bordeaux to Bayonne, a distance of 100 miles. It may be added that in this sand (which, in some places, is 100 ft. deep) they had to excavate several mètres before securing a sound foundation for footings. This difficulty being overcome, the walls were then carried up battered on the outside from a mètre thick at footings to thirty-five centimètres (1 ft. 2 in.) at plinth level, and then proceeded with in the ordinary way. In some places retaining walls were necessary to keep up the sand, the pressure being very great, especially after rain, when it is apt to slip a little.

The sand is fine and light coloured, rendering it useful for building purposes, and that which was excavated was used for the mortar. The house is built of red brick (*brique de Nercam*) with a white flat joint, and white stone dressings (*pierre de Nersac*) with black pointing, that below the plinth being random work, also pointed in black.

The roof is of slate, and made to overhang some 5 ft. in order to shade the house from the sun, which has great power there. Great care has been taken in carrying out Messrs. Drysdale and S. W. Hayward's Patent System of Warming and Ventilating, but owing to the plan being of an irregular shape, it was a somewhat difficult task to procure a straight and convenient passage for the foul-air flue, so as to render it easy of access at any time for repairs, if necessary.

The architect was Mr. George Fred. Haines, of Boscombe-road, Shepherd's-bush. The works were executed by M. Blavey, contractor, and M. Martin, carpenter, of Arcachon, a great many things being provided by English firms: Messrs. Steel & Garland, Sheffield, providing the grates; Messrs. Minton Hollins and Messrs. Maw & Co. providing tiles for the grate cheeks, hearths, &c.; Mr. Geo. Jennings's patent w.c. apparatus being used, and wooden sinks for scullery and butler's pantry, with hot and cold service laid on throughout the house. Credit is due to Mr. H. J. Ellison, builder, Bournemouth, by whom the pine doors and windows were worked and fixed, as also the oak chimney-pieces from the designs of the architect.

A VICTORY OVER SEWER GAS.

Sir,—1. For more than seven years I have been watching the progress made in house sanitation, and I have passed through many experiences. I will not give those at Birmingham and Manchester, where the local administration is prompt and effective, or at Hampstead, but confine my observations to Philbeach Gardens, near Earls-court, where, influenced by the excellent and very advanced sanitary arrangements which have been matured, I have bought a house. I send you plans of them,* and will relate by what steps of evolution the success has been obtained.

2. On the 30th of June, 1880, I took No. 106, Philbeach Gardens, S.W., on a short lease, on trial, of Mr. Mineard, the builder, on the condition that there should be no escape of sewer gas into the house. The house was like others built on the estate some three or four years ago, with a syphon trap under the coal-cellar, and the soil-pipe continued open up to the roof.

3. At this time Mr. Mineard was building other houses on the estate, in which he had introduced an intercepting-chamber between the main sewer and the house drainage, as well as a ventilating-channel at the adjacent wall. Accordingly, the first thing Mr. Mineard did was to fit up my house similarly to others he was then building, with an intercepting and inspection-chamber, and with an inlet for fresh air through one of Boyle's ventilators in the front area. I found Mr. Mineard unusually interested in the progress of house sanitation, and well acquainted with what his brother builders were doing, and

* The details on Plate 2 are drawn rather less than one-fifth of full size.

the many systems which sanitary surveyors were recommending. I was by no means perfectly satisfied that traps of any kind could be relied upon as absolute preventives, and I objected to using the stack or soil-pipe for upward ventilation, which is commonly done, and was done in my house. I urged the necessity of an independent upward draught, which I had insisted upon having introduced into my last residence at Hampstead.

4. Mr. Mineard himself admitted that the best systems then in use were not, in his opinion, satisfactory, but contended that it would not do for a builder to be endeavouring to excel in sanitary work; because whatever he might accomplish in that direction was likely to be much criticised, and, perhaps, unfavourably, by the self-styled sanitary engineers, who might happen to be called in to report on his houses, especially if it differed at all from the engineers' own pet plan. He expressed an opinion that he could do something better than anything then in use, and asked me to allow experiments to be made on my house, to which I cheerfully consented.

5. He proceeded to close up the inlet ventilator to the intercepting-chamber, and connected therewith instead an outlet ventilating shaft of wrought iron, carried above the roof of the house, with a small heating-chamber about 5 ft. above level of area, trying experiments with gas and various kinds of burners, atmospheric and otherwise, and his success from the first was complete. More gas at first was used than was necessary. The results now prove that about 2 ft. consumption of gas per hour is ample to draw down the air which passes down the soil-pipe, then through house-drains and up the extracting shaft.

6. The gas was first applied to No. 106, Philbeach-gardens, in the early part of February, 1881, and Mr. Mineard took out his patent on the 15th of April, 1881.

7. While I write this, the following facts have been registered at the south aspect of my present house, 96, Philbeach-gardens:—

1st. With both w.c.'s closed, the length of pipe from inlet on top of soil-pipe to top of extracting shaft is about 160 ft., and the air passes through the anemometer at the rate of 384 ft. per minute.

2nd. When the upper w.c. is open, which, acting as inlet to soil-pipe, reduces the length of pipe to 140 ft., air passes through at the rate of 422 ft. per minute.

3rd. When the lower w.c. is open, reducing length of pipe to 115 ft., air passes through at 440 ft. per minute.

8. These facts were obtained on 16th September, 1881, at 3 to 3.30 p.m. The day was fine, little air stirring. The sun shone on the front of the house and helped the extraction.

9. The simple effect of these arrangements, which can be demonstrated to any one, has been to produce an *upward* draught so potent that the *downward* draught in all parts of it extinguished a lighted match; and so the problem of giving absolute security against the possibility of sewer gas entering a house was thus solved.

10. The cost of the gas I estimate to be about 1s. per week, which I consider a cheap insurance against typhoid fever.

11. Whilst the work described in No. 106 was going on, Mr. Mineard was erecting further houses ten doors off. These, in general arrangement, were greatly improved. The highest authority on practical sanitation said my present house was "the largest on the smallest space he had ever seen." Upon Mr. Mineard agreeing to introduce some suggestions which I made, I bought one of them, No. 96, and I now invite my friends to come and see it, and criticise it. It exhibits:—

I. Plenty of light—an antidote to dirt and slattishness.

II. Good ventilation generally, and special means for preventing the usual escape of kitchen odours in the passages of London houses.

III. Absolute extraction of all sewer gases and smells by Mineard's patented sanitary arrangements.

IV. Security against frozen water-pipes and water in cisterns.

V. Heating in passage at no cost for working.

VI. A labour-saving lift from kitchen which also insures hot viands and plates.

12. Mr. Mineard has reaped his reward for his intelligent attention to sanitary science, and the practical application of it. He sells his houses with these sanitary features at increased profit before the houses are completed; and since the first experiment was made, has introduced them into all the houses he has built, and is now building.

13. His patent for the application of this system of extracting sewer-gas covers, also, any method of heating, and I have no doubt he will devise a means of cheapening the heating.

14. The result he has now arrived at, by slow but progressive and sure steps, has been the work of four years; and I believe he is only at the threshold of further successes, and that his system will be found applicable at little cost to houses smaller than the one I live in. The plans sufficiently explain themselves without further observations. HENRY COLE.

PRINCIPAL FAÇADE, CADIZ CATHEDRAL.

IT would be in vain to search in the comparatively modern edifice of Cadiz Cathedral for records of the great traditions impressed upon the Gothic pillars of other churches of Spain. The written history of Cadiz Cathedral can scarcely be traced; but, in its place, the building itself is valuable as an artistic work, and a silent testimony to the religious fervour of the people and to the perseverance of Bishop Don Fr. Domingo de Silos Moreno, whose statue, in bronze, was erected in the cathedral square by the municipality in 1856. The foundation-stone of the church was laid on May 3, 1722, during the episcopacy of Don Lorenzo Armengual de la Motá; and the work was commenced under the direction, and according to the plans, of the architect, Don Vicente Acero. Want of funds, however, caused the work to be stopped, and for almost a century nothing was done, the completed portion in the meantime greatly deteriorating. In 1832, when a fire broke out amongst the timber stored in one of the chapels, Silos Morenzo, the bishop at that time, succeeded in stirring up public feeling in the matter, and mainly by his exertions the building was completed, so that he had the satisfaction of consecrating it on November 28, 1838. The sums spent in the construction of the cathedral up to that time amounted to twenty-six million reales.

The interior of the church consists of nave, aisles, and fourteen chapels, and is richly decorated with marble and jasper. The nave measures 279 ft. in length and 44 ft. 6 in. in width; the aisles are 25 ft. wide. Its greatest height, from the pavement to the roof, is 173 ft. The façade has an elevation of 68 ft. 6 in., and has three entrances. It is flanked by two octagon towers of a height of 189 ft., and a diameter of 44 ft. These towers were erected under the direction of the architect, Don Juan de la Vega; the eastern tower was finished in 1846, the western in 1862. The columns of the façade are partly of the Ionic, partly of the Corinthian order. Two niches in the façade contain the statues of St. Servando and St. Germano, the patrons of the city, and possessing some claims to antiquity. They were saved from the ancient cathedral of Cadiz, which was burnt down at the time of the English expedition against the city in 1596. They found a place in a new building, still known as the old cathedral (*catedral vieja*), and now used in connexion with the present cathedral.

We cannot attempt to describe the building in detail, but may mention a few of the more salient features. The abundance of marble amounts to prodigality, yet without exceeding the bounds of good taste. Visitors are further struck by the elegance and grace of the presbyterium, the excellent execution of the pavement, and the handsome choir-seats, the work of the famous carver, Pedro Duque Cornejo, and which formerly belonged to the Carthusians of Santa Maria de las Cuevas of Seville. These seats were placed in the cathedral in 1859. The choir screen also deserves mention, as well as the magnificent tabernacle, finished in 1866, and in which is preserved a valuable bronze ciborium. There is also a richly-chased silver chalice here, the work of Antonio Suarez (1664).

A Useful Machine.—The *Cambridge Chronicle* says that Mr. G. Hamit, engineer to the Haddenham Drainage Commissioners, has invented a machine for cutting weeds, or what is commonly called roading rivers, drains, and watercourses. The adoption of this new machine will reduce the cost of "roading" by at least one-half, besides doing the work in a quicker and superior manner. It cuts the weeds and collects them in heaps for the men to gather.

CHURCHER'S COLLEGE, PETERSFIELD, HANTS.

THE Governors of Churcher's College having invited six architects to submit designs in competition for the new College buildings, received the drawings in December, 1877, and submitted them to Mr. Ewan Christian, the architect to the Ecclesiastical Commissioners, to report on their respective merits. In accordance with that report, the design marked "Thoro," submitted by Mr. G. R. Crickmay, of 17, Parliament-street, Westminster, was chosen, and, with slight modifications, has been carried out under his superintendence. The present commodious and substantial building is the result.

The college has been planned in accordance with the modern requirements of a public school. We understand that the building has undergone a critical scrutiny by several experienced masters of public schools, who expressed their approval of the arrangements.

The building is planned with the head master's house at the south-west corner; the kitchen and matron's department at the north-west corner; and the school running eastward from between the two.

The school is arranged with rooms on each side of a corridor, and consists of a spacious dining-hall, library and committee-room, assistant master's sitting-room, class-rooms, and at the extreme east end a large and lofty school-room; and on the floors over are the dormitories for the boys, the assistant masters' bed-rooms, lavatories, bath-rooms, wardrobe-room, &c. The head master's house consists of three sitting-rooms, seven bed-rooms, dressing-room, and domestic offices, and although entirely shut off from the school, it is in such close proximity that he has the complete control of the school, dormitories, and matron's department. The matron's department consists of the kitchen, scullery, and offices, her own sitting-room and bed-room, and the servants' hall and bed-room. The kitchen is connected with the dining-hall by a pantry and servery.

Accommodation has been provided for fifty boarders and 100 day-boys, and provision has been made for future extension, the kitchen and matron's department having been constructed sufficiently large to meet the requirements of a larger school.

It is proposed to erect a gymnasium and fives-court, and a laundry is provided on the east side of the educational block.

The building has hollow walls, and is faced with Godalming Bargate stone with Box-ground stone dressings, the roof being covered with Hamworthy Junction plain tiles, the whole forming a picturesque group. The staircase and corridors are fire-proof. The floors of school-room, class-rooms, dining-hall, and library, are formed of wooden blocks laid herringbone-wise. Open fireplaces have been provided throughout, and Capt. Galton's ventilating grates are used in the dining-hall, library, school, and class-rooms. The principal rooms are finished with trowelled stucco for paint, and with Parian cement dado. Considerable attention is said to have been given to the sanitary state of the premises, and in no case does a drain connect with the school buildings. The premises are supplied with water, and gas has been laid on throughout. The gardens, cricket, and recreation-grounds are about ten acres in extent, and the surrounding country is very picturesque.

The buildings have been erected at a cost of something over 10,000*l.* by Mr. John Crook, of Southampton, Mr. Hawkins being the clerk of the works. Messrs. Lankester & Son, of Southampton, were the contractors for the gas, bell-hanging, and hot-water work.

Practical Christianity. — Archdeacon Denison has circulated in Brent Knoll, in Somerset, a paper setting forth the extent to which he has, during the last quarter of a century, supplied the district with water. Finding that epidemic disease prevailed for want of water, he dug for wells, and has now ten reservoirs, four springs, and eight dams with fountains, filter-beds, tanks, and pumps. The drinking-water is supplied through galvanised pipe directly from the springs. The six lower reservoirs are fishpools, pools for swans and ducks, and drinking-places for cattle. The Archdeacon has spent 1,500*l.* on the works, and he now calls upon the people to take up the matter themselves.

CHURCHERS COLLEGE : PETERSFIELD . HANTS :

IMPROVEMENTS AT SOUTHPORT.

NEW MARKETS AND PROMENADE.

On the 7th ult. the new markets in Southport,—perhaps the most progressive of watering-places,—were opened by the Earl of Derby. The markets, situated in Eastbank-street, have been erected in the Italian style of architecture, from the designs and under the superintendence of Messrs. Mellor & Sutton, architects, London-street, Southport, Mr. Leigh Heyward being the clerk of works, and are bounded by streets on three sides, with thirteen entrances therefrom, the centre entrance to Eastbank-street having pilasters and columns, supporting figures of Flora and Ceres. Over this entrance will be a clock, to be seen from both the inside and outside of the building, and on the top of the pediment a group of sculptured figures. Surmounting behind is a large octagonal dome, covered with zinc, of fish-scale pattern. The central entrance in King-street is surmounted by a bell-turret, supported by Tuscan columns, pilasters, &c. All the details have been carried out in a bold manner, suitable to the general character of the building, and the whole of the three elevations are faced with Longridge stone. The market is spanned by five bays of principals supported on iron columns and lattice girders, well lighted from lantern-lights in the centre of each bay, arranged so as to exclude the sun's rays as much as possible from the area of the market. The inside of the market is divided into three parts, that for the poulterers, butchers, provision dealers, and greengrocers occupying an area of about 2,660 square yards, the greengrocers occupying the centre, their stalls being in eight blocks of four each, so as to give them a fair chance of equal patronage by each occupying a corner. Cold water is laid on at two points in each block, with standpipe and tap, and sink under. The butchers, poulterers, &c., are ranged round the sides in thirty-five stalls, each having water supply, small stove for cooking, &c. The walls are lined with glazed white bricks to 5 ft. high; the provision stalls have revolving shutters; and the floor of the stalls throughout, with the exception of the greengrocers', are laid with wooden blocks on a bed of cement. The fish-market occupies an area of 719 square yards, and contains twenty-seven stalls, fitted with earthenware sinks, with water supply over the same, and grid underneath, marble fish slabs, small stove, &c. The wholesale portion of the market, which is at the rear of the fish-market, and can be entered therefrom by two doors, or from the butchers' stalls, or from Market-street, contains an area of 824 square yards. The inspectors' office is placed here, and is in two stages. In his office will be the large gas-meter, and he will have control of the weighing-machine, which is placed in Market-street, and is overlooked from his office. Close to this office is a stand-pipe and tap for hot water, to supply the butchers, &c., with hot water for washing purposes. The market-yard is in connexion with the wholesale market, and contains receptacles for fish and vegetable refuse, boiler-houses, &c., and cart-entrance from Queen Anne-street. There is a basement story under the whole of the market for storage purposes. It is approached by an inclined way adjoining the market-yard, and by steps from King-street. The whole of the works have been carried out in a creditable manner by Messrs. Bridge & Son, of Southport and Burscough. The building has cost about 25,000*l.*, and the freehold (which was bought in 1876) cost about 15,000*l.* An Act empowering the Corporation to proceed with the work, and borrow 50,000*l.* for it, was obtained in 1876. It will, perhaps, be remembered that about four years ago, when the Corporation offered a premium of 100*l.* for the best plan for a new market to suit the site, subject to certain conditions, a controversy arose on the subject of the selection of the plan. Three plans were chosen out of twenty-five designs sent in, but as the committee could not agree upon the merits of the three, they were submitted to Mr. Waterhouse, upon whose decision was to rest the award of first, second, and third premiums. Mr. Waterhouse awarded the first premium to a design by Messrs. Coe & Jackson, of London, the second to Messrs. Bell & Roper, and the third to Messrs. Mellor & Sutton, a local firm. With this decision certain members of the Markets Committee were not satisfied, and a meeting of that committee was held to decide the question. At this meeting (says the *Liverpool Post*) Mr. Alderman Sutton (the present mayor and a brother to the local architect) presided, and it was by his casting vote that the design selected as first by Mr. Waterhouse was discarded in favour of the design of Messrs. Mellor & Sutton. This led at the time to much severe comment in the local press of an exceedingly personal character, and although public opinion seemed to discover in this vote of the committee a prejudice which was not altogether the outcome of purely artistic yearnings, the local plan was sanctioned by the Council and triumphantly proceeded with. The committee was of opinion that the Mellor & Sutton plan, "with a few modifications," would meet the essential points defined by Mr. Waterhouse in his report, and recommended that that firm should be "called in." The amount originally intended to be laid out in the structure was 15,000*l.* Among the "instructions to architects" in the competitive designs issued by the committee, was one distinctly stating that "the total cost, including architect's commission, must not exceed 15,000*l.*" The present market has, we are informed, cost upwards of 10,000*l.* more than that amount.

The New Promenade.—The new Marine Promenade, being an extension northward of the Promenade as it existed in 1879, was opened on the same day by the Earl of Lathom. The ground upon which the new promenade is formed cost 8,000*l.*, and the contract for its reclamation, including the formation and paving of road and footways, amounted to nearly 32,000*l.*, the contractors being Messrs. Gripper & Baylis, of London, who have occupied about two years in the work. Forty-eight acres have thus been reclaimed and built up as a continuation of the promenade, which now extends close up to Hesketh Park, the entire promenade being about a mile and a half in length, of which the extension is three-quarters of a mile. The whole of the work has been carried out from the plans and under the supervision of Mr. William Crabtree, the Borough Surveyor, who has prepared a plan showing how the land reclaimed may be made to afford sites for 144 villa residences, all detached.

The "Palace Hydropathic and Spa Hotel."—A new wing to this establishment was opened on the 9th ult. Mr. Littlewood, of the firm of Mangnall & Littlewoods, architects, Manchester, before commencing the designs, visited the most noted hydropathic institutions at home and abroad, and as, we are told, has concentrated all their several excellences in the Palace Hotel. The exterior, which is in harmony with the general character of the old building, is picturesque, the sky-line being well broken up. The wing communicates with the main edifice by means of a wide corridor, from which access is gained to the new dining-room. Beyond this is the recreation-room, a large apartment, with an ornamental coved ceiling, and pilasters of composite design, dividing the wall into panels. This room will be used for concerts, amateur theatricals, and other amusements. At the end of the corridor is a door giving access to a second corridor, lighted from above by means of coloured glass, and perfectly ventilated. The walls are decorated with a dado of tiles, of artistic design. Leading off from this passage are gentlemen's baths, of all kinds, all of marble. To each bath two dressing-rooms are attached. At the end of the corridor is the Turkish bath, a lofty room terminating at one end with an apse, into which stained-glass lights are introduced. Attached to this bath are dressing-rooms and a smoking-room. The ladies' baths, which are similar in style to the gentlemen's, are reached from a corridor on the opposite side of the wing. The baths have been erected under the personal superintendence of the architects. They are approached by the principal drive, but have an entirely distinct entrance of their own. The recreation-room is one of the largest rooms of the kind in the kingdom. It is 80 ft. long, 40 ft. wide, and 25 ft. high. Turkish, salt-water, medicated, electro-magnetic, shampooing, and douche baths, and an inhaling-room, are included in the accommodation provided.

The Baths of Agrippa Unearthed.—The excavations undertaken for isolating the Pantheon have laid bare in the Via Della Palombella the baths of Agrippa. The floor, some six mètres below the level of the street, is strewn with fragments of cipollino marble. The base of a column of the same material, fluted only on one side, and a mètre in diameter, is also visible. An immense fragment of cornice, which surmounted it, has just been unearthed.—*Daily News.*

POLITICS AND THE TRADE UNIONS CONGRESS.

Sir,—Surely the almost exclusively political character of the proceedings of the Trade Unions Congress is greatly to be regretted. It is not easy always to draw the line between those considerations which may affect the welfare of any particular trade, or, indeed, of any collection of trades, and those which refer to the political institutions of the country. But it should be remembered that there is a very great contrast in the conditions under which the two categories of subjects can be approached in any such meetings as those referred to. As to the welfare of a trade, regarded as a guild, or fraternal association of masters, journeymen, and apprentices, or anything approaching that ancient and honourable order, the members have special information. Each class or grade in such a trade knows what affects itself most readily, and it may be of common service to hold such a parliament of trades as shall bring this special information under full and intelligent discussion.

With regard to political discussion, on the other hand, there is no subject which demands such broad and accurate knowledge rightly to approach. It is not a matter as to which knowledge is instinctive, or which the special experience of an individual, or of a small class of individuals, has any but an infinitesimal value. Politics is one of the most difficult, as it is one of the most important, of human sciences, and it is only as a science that it can be studied or approached with advantage. The idea that the reference to a few axioms or supposed necessary truths, joined to some fluency of speech, and a good deal of earnestness of purpose, is enough to make a man a politician, is not only false, but mischievous. To be able to form any clear and correct opinion on a political question requires a large amount of accurate and well-based historical knowledge. The leading problems in politics are few. They were discussed by the highest human intelligences, under the most favourable circumstances, two thousand years ago, and though conditions have since then widely changed, principles remain the same. For any man to be able to form an opinion that is worth two straws on any question of politics, in the higher sense of the term, he must know, first,—what are the elements of the great political problems; and secondly, how the relation of those elements has been illustrated by the whole course of ancient and modern history. To historic knowledge down to the present day must be added a considerable amount of statistical knowledge. And all this must be guided by practical acquaintance with the laws of thought and with the nature of logical sequence.

A fit education, therefore, for a political speaker is hardly possible out of those classes in which a certain degree of affluence admits of the devotion of a considerable number of years to the acquisition of a very sound education. Among those young men who are training to compete for the daily more difficult entry to the Civil Service, the Bar, the Church, the Army, the Medical, Architectural, or Engineering professions, there are few who have ever an hour to spare for the systematic study of politics. The exigencies of competitive examination are daily narrowing, and, in my opinion, impairing, the education of the more educated youth of England. And as to those who have to go early in their teens to the plough, the loom, the forge, or the shop, any education in one of the highest branches of human study is entirely out of the question. What is the result of the discussion of such a subject as the effect of vaccination by men ignorant of the very rudiments of physiology, of pathology, or of therapeutics? What ideas of the movement of the heavenly bodies can be formed by persons wholly ignorant of geometry, and of the special branch of trigonometry? What idea of the art of war can be formed by a man who has never seen a more orderly muster than that of a flock of sheep or a drove of pigs? Knowledge, it must be remembered, is only to be attained by hard, patient, and unintermitting study. The higher grades of knowledge are only to be attained by those who have patiently and faithfully passed through the lower grades.

For this reason all such counsels as tend to divert the studies and the energies of any class of men to matters which their education has not fitted them to grasp, and for the mastery of which they have neither the leisure

nor the preparation, must be regarded as mischievous. Nor can it be helped if this opinion seems to bear as hardly on certain discussions in Westminster as in yet more recent debates in St. Andrew's Hall.

An Old Hand.

SAFETY IN RAILWAY TRAVELLING.

Continuous foot-boards, door-locks for carriages, and other appliances intended to ensure safety in railway travelling, were discussed in a paper read by Mr. R. Pickwell before the Mechanical Section of the British Association. The author referred to the importance attached by the Board of Trade to continuous foot-boards, &c., and other means of reducing the possibility of accidents occurring. After giving statistics as to the number of passengers killed and injured by falling between trains and platforms, or in attempting to enter or alight from trains in motion, and the compensation paid for personal injuries, the author explained the working of an appliance connected with a railway carriage door on view in the room, his description being as follows:—The machinery and automatic arrangements attached to the carriages are so arranged that the carriage-doors are no longer entirely in the hands of the passengers, but under the absolute control of either the engine-driver or the guard, and operate as follows:—When a train is standing at a station platform, and taking in or setting down passengers, all the carriage-doors are released, and can be opened and closed at pleasure, as is the case with the existing carriages, and no difference can be observed between the patent and the existing carriage-doors; but the dangerous space between the foot-boards and the station platform (usually a few inches), and which the Board of Trade call special attention to, is bridged over throughout the length of each carriage by a movable foot-board placed over the usual one, which, by the arrangement, is always kept in this position whenever the train is standing at a platform. When the time for departure arrives the signal is given by the guard, and the engine-driver by means of a valve, at one operation, gently closes all the doors left standing open, and locks the whole of the doors from end to end of the train, at the same time the movable foot-board is withdrawn to a position over the existing foot-board, and the train travels to the next station. On arriving at the next platform the engine-driver, by a similar operation of the air-valve, instantly releases all the doors from end to end of the train, and at the same instant the movable foot-boards advance outwards, and completely bridge over the spaces between the platform and the wheels as before; in this position passengers can alight from the train as at present. On leaving the platform again the same operation is gone through, as already described. In closing the carriage doors no serious accident need occur by a passenger being trapped in the act of entering a carriage, as, at the time of closing, a signal-bell would be struck on each carriage, and the doors can be closed as slowly as may be desired; and, in addition, a spring-box is attached to the closing levers, so as to enable a passenger, if so caught, to push the door open and release himself, after which the door will at once spring to and become locked, the same as all the rest of the doors. The whole of the apparatus is made to act automatically, so that in case of collision or break away the whole of the doors from end to end of the train would be liberated automatically, and the passengers could leave the carriages at will. As the operation of opening and closing may be instantaneous, or may be regulated at will, no time need be lost on arriving at a platform in releasing the doors; and again, on leaving the platform, the doors being closed all at one time, may be done so more slowly than at present, and the chance of trapping is prevented; which frequently happens at present, when one porter has to rapidly close the doors of a whole train as it passes on leaving the platform. The author believes that were the above appliances in use, that class of accidents which form such a large percentage of the whole would be greatly reduced, such as falling between carriage wheels and platforms, alighting from and entering trains in motion, closing doors, and falling out of carriages whilst in motion. Should a passenger fall in entering or alighting from a carriage whilst standing at a platform, he cannot get between the wheels and the platform; whilst the possibility of persistent travellers entering or alighting from carriages whilst in motion is prevented, the doors being locked until the moment the train stops. Also the possibility of a carriage door flying open, and passengers falling out is prevented, the doors being locked until the next platform is reached. The foregoing are the advantages to the public to be obtained from the adoption of this system. The railway companies are perhaps as interested in the matter as the public, but from an economic point of view. The amount paid for accidents by the companies of the United Kingdom may safely be said to amount to 200,000*l.* annually.

THE DUBLIN SCIENCE AND ART MUSEUM COMPETITION.

In this competition, advertised in our pages, sketch designs are to be first sent in, from which a committee, including at least one architect, will select five. The authors of these will be invited to enter into a final competition, carrying out strictly their original proposals, and each will receive 150*l.* towards expenses. The competitor ultimately selected is to receive a fixed sum equal to five per cent. on the amount the Treasury may authorise to be expended on the building. The sum stipulated for the entire cost is 100,000*l.*

ARCHÆOLOGICAL NOTES.

Berks Archæological and Architectural Society.—About thirty members of this society, under the guidance of Mr. W. L. Nash, of Reading, the hon. secretary, paid a visit to Basingstoke on the 22nd ult. The party proceeded to inspect the ruins of the Chapel of the Holy Ghost, and also the Parish Church. The Rev. Dr. Millard pointed out the features of interest in both buildings. The party then proceeded to Basing Church, where Dr. Millard, at the request of the Vicar of Basing, again acted as guide. The ruins of Basing House were next inspected, under the guidance of Mr. C. F. Cooksey, the hon. secretary of the North Hants Archæological Society, who read a paper upon the history of the place. On the return of the visitors to Basingstoke, they were entertained by the Rev. Dr. Millard, as president of the local society, at the Old Angel Café.

Discovery of a Roman Monument at Hexham.—The *Newcastle Courant* says that on the 21st ult. a remarkable Roman monument was discovered in the porch of Hexham Abbey Church. Mr. Hodges, an architect, now engaged in bringing out a series of illustrations of the church, and Mr. Robert Robson, the clerk, while excavating in the Slype came upon a large slab a few feet below the surface. On further investigation, a monument, about 7 ft. long and 3 ft. 6 in. wide, in a good state of preservation, was disclosed, the upper portion containing a figure of a mounted warrior, bearing the Roman standard, with his horse in full career, and a conquered foe at his feet. Below this is a tablet with the following inscription:—

DIS MANIBVS ELAVNVS
LQ ALAE PETR SIGNIFER
TVRCANDIDI AN XXV
STIP VII H S

From this inscription it would appear that the hero of this monument was a standard-bearer in the Troop Candidi of the body of cavalry known as the Ala Petriana.

ALL SAINTS', SOUTH LAMBETH.

The Church of All Saints, South Lambeth, built some three or four years since by the firm of Messrs. Lucas Bros. at a cost of 13,500*l.*, exclusive of the site (1,200*l.*), has already been found too small for the crowded congregations assembling there. Mr. Sidney Smith, architect, was instructed to draw plans, &c., for the addition of transepts, and these are being carried out, and just reaching completion, by Mr. Wm. Shepherd, of Bermondsey New-road.

The congregation requested the southern transept to be made as a memorial of their love and esteem for the vicar, and to their credit be it said that though in five years, directly and indirectly, they have raised 14,000*l.* for the building, &c., of the church, yet in six weeks they have again promised a sufficient sum to cover the expense of the new transept.

PATENT RECORD.*

APPLICATIONS FOR LETTERS PATENT.

3,911. J. Wetter, New Wandsworth. Reflectors. (Com. by W. Wheeler, Massachusetts, U.S.A.) Sept. 9, 1881.

3,961. R. H. Reeves, Parkhurst. Construction of drainage for the purpose of destroying noxious gases, &c., arising from sewage. Sept. 14, 1881.

3,968. F. T. Bond, Gloucester. Heating water for domestic purposes, including an improved gas-burner. Sept. 14, 1881.

3,972. S. C. Davidson, Belfast. Stoves, &c. Sept. 14, 1881.

3,985. H. H. Lake, Southampton-buildings. Door and other knobs. (Com. by C. C. Harrington, Newton, U.S.A.) (Com. spec.) Sept. 15, 1881.

NOTICES TO PROCEED

have been given by the following applicants on the dates named.

Sept. 13, 1881.

2,000. E. Edwards, Southampton-buildings. Wrought-iron window-frames. (Com. by C. A. Schütz, Stralsund.) May 9, 1881.

2,040. P. Jensen, Chancery-lane. Production of artificial stone or composition, &c. (Com. by E. J. Erichsen, Copenhagen.) May 10, 1881.

3,620. J. Craig, Kilmarnock. Dressing enamelled bricks, tiles, or slabs. Aug. 19, 1881.

3,826. E. L. Dietz and M. A. Dietz, Oakland, U.S.A. Dust-pans. Sept. 2, 1881.

Sept. 16, 1881.

2,059. A. Guattari, Covent-garden. Producing upon marble, &c., designs, in imitation of sculpture. May 11, 1881.

2,087. G. Osborne, Brighton. High-pressure regulating taps or valves. May 13, 1881.

3,081. W. Dawes, W. H. Thompson, and D. Thompson, Leeds. Water-closets and urinals. July 14, 1881.

3,811. H. Hall, St. Pancras. Tiles for facing or lining walls, &c. Sept. 1, 1881.

ABRIDGMENTS OF SPECIFICATIONS

Published during the Week ending Sept. 17, 1881.

505. T. Rowan, Ryde. Chimneys or flues.

To provide an effectual up-draught, the flues open into a chamber from which passes a shaft on the top of which is a cowl to produce an induced current. To purify the smoke an additional chamber is fitted above the former chamber, which is supplied with a damp porous material. Feb. 5, 1881. Price 6d.

527. A. Clark, New Cross. Water-closets.

The wood framing is dispensed with, and the casing is constructed of porcelain, &c., in one piece with a sloping partition leading to the trap for receiving the contents of the basin. This basin is of the revolving or lift-up kind, and is provided with a flushing-pipe and scraper. Feb. 7, 1881. Price 6d.

540. E. H. A. Herbert, Erith. Apparatus for creating an upward draught in chimneys, shafts, &c.

The chimney-shaft is capped by an elbow, supported so as to be capable of rotation by the air acting on a blade above its horizontal part. Through the vertical part of the elbow is a smaller pipe, with an enlarged mouth-piece, which is presented to the wind, and thus draws out the contents of the vertical portion. (*Pro. Pro.*) Feb. 8, 1881. Price 2d.

550. S. H. Sharp, Leeds. Manufacture of fire-grate card-board ornaments.

These are made of one piece, and an ornamental design is stamped out of them to allow a free passage of air. (*Pro. Pro.*) Feb. 9, 1881. Price 2d.

557. J. Davidson, Auchmill. Draw-off taps of kitchen boilers.

These are formed so as to serve also as safety-valves. The shell has an enlarged chamber, having a horizontal partition across it, which divides the inlet part of the tap from the outlet part. Through the centre of this partition is formed a hole, fitted with a valve with a stem which passes out through the shell, and is fitted with a weighted lever. The tap is opened to draw water off by raising the lever. Feb. 9, 1881. Price 6d.

561. C. D. Phillips, Newport. Roofing tile.

On each of the four sides of the tile is formed a system of grooves with corresponding tenons, so that each tile shall lock into the four surrounding ones. Feb. 9, 1881. Price 6d.

571. H. Mestern, Berlin. Apparatus for ventilating, cooling, and warming buildings, &c.

Two chambers are used, one inside the other, with a space between them. The inner one is open at each end. At the upper part water under pressure is admitted through a nozzle into the top of the inner chamber, into which air also is free to enter. The water ejected from the nozzle with great force fills the inner chamber with a finely divided spray of water, and draws with it the air from the room. The water escapes from the bottom of the outer chamber by a pipe, and the air being released passes up the space between the two chambers, and escapes into the room purified and cooled; or, if hot water issued, heated. Feb. 10, 1881. Price 6d.

* Compiled by Hart & Co., Patent Agents, 28, New Bridge-street, E.C.

581. F. Edwards, jun., Great Marlborough-street. Slow-combustion smoke-consuming grates.

The fire-place is charged with sufficient fuel for the day, and is lighted on the top. A balanced screen is moved down in front of the bars as the fire burns away to expose the fuel to the action of the air. The improvements in this invention are the manner in which this screen is balanced and hung. Casings of metal are attached, one on each side of the front of the grate, and constructed to contain the pulleys and counterweights for the screen. These casings are also flanged or grooved on their inner sides to act as guides for the screen. The grate has a solid bottom. Feb. 10, 1881. Price 6d.

582. J. Sherwood, Birmingham. Galleries of gaseliers.

To one of the arms is pinned a free cranked lever governed by a spring. On the glass being placed in position, the spring presses the lever against the glass. Feb. 10, 1881. Price 4d.

602. L. Appleton, Brecknock-crescent. Appliance for preventing the bursting of water-pipes by frost, &c.

This is a vent-tap or cock, which, in addition to the usual passage, has a lateral aperture communicating directly with the main passage of the plug, and allows air to flow into the pipe when the cock is closed. (*Pro. Pro.*) Feb. 11, 1881. Price 2d.

EDINBURGH.

The Burgh Engineership.—Mr. Fraser, the burgh engineer, has resigned his office on account of ill-health, but he will continue to act as consulting engineer. The sub-committee of the Lord Provost's Committee, appointed to prepare a report on the duties and salaries of the officer to be appointed in the room of Mr. Fraser, as also with reference to the management of the streets and foot pavements, previously to steps being taken for filling up the vacant office, have resolved to recommend that the supervision of pavements should be transferred to the Roads Department, and Mr. Proudfoot's salary continued at 400*l.* a year, the new burgh engineer, in consideration of the advice to be afforded by Mr. Fraser to the gentleman appointed, to receive a salary of 300*l.* An amendment to the effect that an experienced engineer should be appointed at a salary of 500*l.* was negatived.

The Old Infirmary Buildings.—The sub-committee of the Treasurer's Committee of the Edinburgh Town Council, charged with the arrangements for the conversion of the portion of the Old Royal Infirmary buildings, purchased by the Corporation for the purposes of a fever hospital, have (according to the *Scotsman*) instructed Mr. Morham, the City Architect, to proceed with the preparation of the necessary plans; the burgh engineer, to examine and report as to the drainage; and Dr. Littlejohn to report as to the allocation of the wards for different kinds of infectious diseases.

MONUMENTAL.

The Eurydice Memorial.—A monument, the preparation and erection of which has occupied twelve months, has been placed in Haslar Naval Cemetery, to the memory of the officers and men who were lost in the training-brig *Eurydice*, in March, 1878. The base, which is of polished granite, and records the names of 316 officers and men who went down, was prepared by the convicts at Chatham, while the superstructure was prepared by the convicts at Portland, with stone from the neighbouring quarries, and resembles a huge rock, which is surmounted by the real anchor of the *Eurydice*, embedded in the rock. The memorial was designed by Colonel Pasley, R.E., director of works, and it has been erected by the Works Department of the Navy.

The late Dean Stanley.—The daily papers say they have reason to believe that it is the intention of Dean Stanley's successor to take an early opportunity of calling a meeting to consider the best mode of raising within the walls of Westminster Abbey a monument to his lamented predecessor. It is understood that a proposal which has already received influential sanction, as both appropriate in itself and likely to receive wide and general support, is that of an altar-tomb, with recumbent statue, to be placed in the Chapel of Henry VII., in the immediate vicinity of the grave in which the remains of the late Dean were so recently laid by the side of those of Lady Augusta Stanley.

Torquay.—The Local Government Board have sanctioned a loan of 3,000*l.* for the purpose of erecting a Sanatorium at Torquay. Mr. Ernest Turner, of Regent-street, is the architect.

TECHNICAL EDUCATION FOR "THE UPPER TEN."

MURAL DECORATION.

SIR,—Notwithstanding the labours of a most efficient Royal Commission of some forty years past, and all that has been written since on mural decoration, the crass ignorance on the subject appears to remain as unshaken and as immovable as ever. For instance, in your leader of Sept. 17, you have to call attention to the flagrant violation of so elementary a principle of decoration as that against introducing pictorial glass into chambers in which mural painting is destined to play a conspicuous part. The two are incompatible. This was authoritatively laid down in the reports of that Royal Commission; how uselessly, we see, from the fact that the very chambers in which the members of that Commission used to meet and deliberate are being treated in direct contravention of the precepts they had so carefully gathered to guide the decoration of the palace at Westminster. But knowing, as all men who have carefully studied the history of art know, how important the encouragement of mural painting is to national art, no stone must be left unturned in the endeavour to help the *dilettanti* to a better understanding of the subject. I therefore beg leave to subjoin a few concise memoranda upon the noble art of mural painting.

1. In the decoration of a building, pictorial glass and mural pictures are incompatible; for neither oil, fresco, nor encaustic colours can compete with the chromatic brilliancy of glass. Grisaille, with a small plaque of moderated colour, is the utmost that should be permitted when mural painting is to be the leading decoration.

2. By far the larger number of the finest paintings ever executed were painted in fresco: were decorative works.

3. Mosaic is an imperfect method of execution, and can only be appropriately employed in out-of-the-way spaces,—spaces far removed from the eye.

4. The execution of mosaic was thoroughly understood in the time of the great Italian painters; nevertheless, it was only sparsely employed, under the foregoing conditions. Perhaps mural painters only can thoroughly understand the ridicule with which Michelangelo and Raffaelle would have received a suggestion that their grand works in the Sistine Chapel and the Stanze of the Vatican should be executed in mosaic.

5. Mural painting is the most difficult branch of the fine arts, requiring long and special training. A painter who has been successfully educated to paint easel pictures may yet be totally unfit to grapple with the conditions of mural painting.

6. The *technique* of fresco painting is much more difficult than that of oil. The permanence of fresco depends on the permanence of the mortar on which it is painted, and we have specimens of mortar as hard as stone after an exposure of a thousand years to this climate.

7. If you want fresco-painters you must raise them. Continued demand would bring efficiency. A great country must be at the cost of some failures in painting, as it has been in some other more expensive matters.

8. The fine-art manufactures attained their fullest development in those two epochs in which painting and sculpture were immediately associated with architecture.

9. Seeing, then, of what vast importance the training for mural painting is to the manufacturers of a country, any one who stands in the way of its adoption in England cannot have the improvement of our manufactures seriously at heart.

10. Mosaic is quite out of court as a method of decoration save and except under those certain conditions we have referred to. But whether in fresco, spirit fresco, tempera, encaustic, water-glass, or even oil, let us have, for the sake of the arts and manufactures of the country, a school of mural painting.

11. It is a common mistake of hon. members to call any painting upon a wall a fresco, whereas they ought to know the term "fresco" is only properly applicable to that kind of painting which is executed in colour and water on fresh mortar; the mortar when dry holding the pigments in its film of carbonate of lime. The vehicle of spirit fresco is wax, oil, &c. Spirit fresco is a new process whose durability is not yet proven. Tempera is colour mixed with size. Encaustic is the use of liquefied wax; the term *encaustic*, however, is ; properly applied to painting with wax when heat is used in the process. Water-glass painting is the use of a solution of silicate of potash over the painting in colour and water on th dry mortar; these colours it incloses in a glaze of silicate.

W. CAVE THOMAS.

THE CHURCHES AND TOWNS OF BUCKINGHAMSHIRE.

SIR,—Is your correspondent, Mr. Joseph Simpson, really under the impression that there are no larger or more beautiful churches in England than that of Newport Pagnell? It would seem so, from the following extract which I have copied from his letter:—

"Does he know Newport Pagnell? Here is a town, although with a population of some hundreds less than 4,000, yet with a church which for size, beauty (both of external situation and internal arrangements), and attendance is not to be surpassed in this or any other county."

Now if the words "size" and "beauty" refer to the church in question, I can only suppose that Mr. Joseph Simpson has never been out of Buckinghamshire, because, leaving cathedrals and monastic churches out of the question, it is simply ridiculous to compare Newport Pagnell Church with any one of the famous Lincolnshire churches,—Louth, Newark, Grantham, Raunds, Higham Ferrars, &c.,—or with the Suffolk churches, such as St. Mary's Bury, Lavenham, Long Melford, Southwold, &c.; or those of Norfolk,—Walpole St. Peter's, Tarrington St. Clement's, Salle, East Dereham, Cawston, Cley-by-the-sea, Worstead, St. Peter's and St. Stephen's Norwich, St. Margaret's and St. Nicholas Lynn; or with the great Yorkshire parish churches, Rotherham, Patrington, &c. But to come nearer home,—to the counties adjoining Buckinghamshire,—does Mr. Joseph Simpson for a moment mean to compare Newport Pagnell Church with that of Leighton-Buzzard, or even with Luton, or with Ewelme, in Oxfordshire? I have not mentioned monastic churches; that would really be too ridiculous.

If the words "size" and "beauty" refer to the "exterior situation" the first of the words is unintelligible, and equally so if they are intended to refer to the "internal arrangements." If Mr. Joseph Simpson means them to refer to the "attendance," I will not argue the point for a moment; I dare say the congregation is large and *beautiful*.

Although Mr. Simpson has kindly attempted to set me right with regard to Buckinghamshire, I fear I must remain in obstinate darkness, if enlightenment means the acknowledgment that Buckinghamshire is a good field for ecclesiology, or that its towns are cheerful and rich in old churches. Look, for instance, at Buckingham, Stony Stratford, Fenny Stratford, Slough, Great Marlow, Wolverton, or even Aylesbury: can they be called lively places, or can their churches be regarded as fine examples of ancient architecture?

Buckinghamshire is one of the very few counties in England which contains no great representative church, and not one monastic church;* nor does it contain any very important parochial churches. The village churches are small and far apart; several of them, I confess, are of considerable archæological interest; such, for instance, as Stewkley, Wycombe, Caversfield, Upton, Wing, Stantonbury, Chesham Bois, Langley, Burnham, Mentmore, &c. These, together with the churches mentioned in the article upon Maids Morton Church, form the chief attractions for the ecclesiologist in Buckinghamshire, and I think I am quite justified in saying that it is by no means a rich county for the ecclesiologist. To compare it with Lincolnshire, Norfolk, Suffolk, Northamptonshire, Somersetshire, and Wiltshire would be absurd, nor can it even hold a place in comparison with the adjoining counties of Oxfordshire, Berkshire, Bedfordshire, Middlesex, or Herts. I may mention the facts that I have visited Buckinghamshire every year for the last

* At Chetwode is a portion of an old monastic church, of very beautiful Early English work, but it can never have been a very important building as to size. The county is remarkably poor in monastic remains; a few fragments alone exist of the Abbeys of Burnham and Nutley. I am told that a part of the cloister still exists at Ashbridge, but I have not seen it. It is strange that although the county once possessed several important castles, not one single stone of any such edifice is to be found at present *in situ!* Buckinghamshire is probably the only county in England of which this can be said.

thirty, and that I have walked over a great portion of the county, and the impressions left upon my mind are, that, with the exceptions of Olney, Hillesdon, and Chetwode, the larger churches are rather poor examples of Mediæval architecture; that the village churches, with few exceptions, are less interesting than those of other counties; and that the towns are singularly dull and ugly, and, as a rule, devoid of objects of antiquarian interest.

THE WRITER OF THE ARTICLE UPON MAIDS MORTON CHURCH.

THE WORD "NATURE" IN REFERENCE TO ART.

SIR,—I have no doubt but that you are right in taking exception to the way in which I expressed myself in my last letter, but at the same time I do not see how this affects the original question,—whether I am wrong in saying "that all ornament should be founded on a geometrical basis." Although this is laid down as one of the "principles" in "Suggestions in Design," it is not intended that it should ignore the fact that there is much ornament which is non-geometrical. I have purposely stated that the principles given are founded upon the practice of art in the *best* ages. If you ask me what I mean by the best ages, I would say, roughly speaking, the Greek and the Early Gothic.

There is, more or less, a geometrical or regular foundation underlying everything in nature, whether it be organic or inorganic, although in its development it is apparently so extremely irregular. When I refer to "nature," I do not confine the expression to one view of nature only, but to nature in its widest and most extended sense,—to the principles or laws, wherever they can be discovered, which can in any way be made applicable to the purposes of ornamental art. I cannot, therefore, consent to be restricted to look at nature in three different ways, or to state "whether I mean according to *metaphysical laws* or *physical laws*." It is true that I may not be able to see far into the hidden laws or concealed principles in nature, and that I may yet be like a child picking up mere grains of sand on the sea-shore; but that such principles are to be discovered, I am convinced, and they may be made available as the groundwork for all art-workmanship.

It may be that I have not stated my position as logically as could be desired, being, as you say, more at home with the pencil than the pen; but all my life I have endeavoured to study nature in this way, searching for principles of growth or formation, which should guide me in the composition of ornament, and not merely for the purpose of copying the physical form. If I take a leaf or a flower as a *motif*, I strive to understand its principle of formation, and work upon that, rather than to imitate the form I see before me, so that my leaf or flower may, apparently, be very unlike that from which it is taken. I may be singular in my notions, but this I believe to be the only true way of applying nature to art, and that all art, in its broadest sense, should be founded upon nature. I cannot, therefore, see that it is necessary or advisable that I should define exactly what I mean by "nature," or whether I look upon it in a *physical* or a *metaphysical* sense. What I advocate is, to take advantage of natural laws wherever they can be perceived, to adopt the external form when suited to the purpose in view, but above all, not to compose anything which is *un*-natural.

JAMES K. COLLING.

CONVEYANCE OF MATERIALS.

SIR,—Some time ago I observed in use at the constructing of the fortifications at Strasburg a method of conveying building materials from one place to another, and have since seen the same in use in America, for conveying goods from the manufactory to the warehouse. I understand it to be an endless wire rope that is kept moving (by machinery) between the factory and the warehouse, and the goods are attached to the rope when passing. Will any of your readers kindly furnish me with the address of parties who fit up such appliances, if there are such in this country? J. A. G.

The Interior of Holy Trinity Church, Leamington, has just been improved by the addition of a carved Caen stone pulpit, with marble shafts, and oak choir-stalls. Brass gas-standards and lectern have also been added. The work has been executed by Messrs. Jones & Willis.

"THE TREATMENT OF CANDIDATES."

SIR,—Your heading and report upon this subject in relation to the recent appointment of Waterworks manager at Middlesbrough calls loudly for some comment upon the manner in which candidates for public offices are frequently treated. We have recently witnessed the creation of several municipal bodies and the farcical proceedings they inevitably inaugurate, of advertising for a staff of officials, when at the same time they have no intention, or the very remotest one, of changing those who have already held office under their tatelary powers as local boards, &c. This, I contend, is altogether misleading and insulting to the intelligence of the men for whom they advertise. Indeed, our Nestors of municipal power seem to be frequently at sea as to what is their plain duty, and the *modus operandi* they ought to and should pursue in the selection of candidates.

I leave you, sir, to imagine the feelings of disgust with which candidates look upon such proceedings, and the contempt which they naturally feel for these "most potent, grave, and reverend signors," and the curses, not loud but deep, for the trouble and expense to which their folly frequently puts many a poor candidate. CONSTANT READER.

LONDON FRONT GARDENS.

SIR,—There can be no question that a small open space in front of a London house, where a tree or shrubs can be planted, does add much, as Messrs. H. & R. Powell point out, to the agreeable character of a street. I am inclined, however, to think that it is most satisfactory if a single tree is planted near the outside edge so as to shade the pavement, or a line of shrubs is placed on this outside edge as a screen, and the interior part covered with plain tiles, on which shrubs or flowers in boxes can be placed. This prevents the untidy and dismal appearance seen in too many front gardens, even on Campden-hill, as the space, if left unadorned florally, is at any rate neat. Nor is a little strip of so-called garden at all times an unmitigated blessing, for in Stafford-terrace, Campden-hill, one of the streets mentioned by your correspondent, the stupid builder has placed the larder beneath the garden, so that it is damp instead of dry. Passing, like your correspondent, the other day along this street, I observed the earth being carried away, and the garden space about to be filled with cement and tiles by some occupier, who, as several other tenants have already done, was remedying the mistakes of the builder.

AN OBSERVER.

MANAGEMENT IN THE WORKSHOP.

SIR,—I am glad to see that you have opened your columns to a communication on the subject of "management in the workshop," and have read with satisfaction the letter of "Observer," in which he mentions some of the evils of the present system. There are, however, several he has omitted, and others which I think should be brought into greater prominence. With your permission, I should like briefly to refer to two or three of these, and in doing so shall speak from my own personal experience and observation. I have known several instances in which young men have come up from the country with slight practical knowledge, but with a friendly introduction to the head foreman. The latter, in consideration of a premium or a weekly present, soon places them in positions for which they are utterly unqualified. Do not suppose this was merely a Christian act. In some cases I know the premium has been 20*l.*, whilst, in others, the man pays his foreman so much "blackmail" every week. The "greenhorn," as I may call him, is generally placed by the foreman with a competent man, who, being thus handicapped with an inferior hand, is unable to get out the work as expeditiously as he would were his companion competent. The consequence is complaints come from the office that a certain job has cost too much, and the next thing is the discharge, not of the friend of the foreman, but of the competent hand, who is sacrificed for no fault of his, whilst his useless mate is kept at the bench to the advantage of the foreman, though to the disadvantage of the employer. If managers or masters would inquire of the men how these unaccountable things occur, instead of leaving everything in the hands of subordinates, they would find it more profitable than the present system. I have known many cases in which quantities of material were spoiled by the incompetence of the setter-out,—invariably a relative or friend of the foreman. Wood sent up to the shop I have known rendered useless for the job for which it was intended, owing to the lengths being wrongly taken off; the rods, whilst in other cases, when (it seemed as if by accident) the sizes were right, there was nearly double the quantity required. This, it is needless to say, showed either gross ignorance or great stupidity, but whichever it was the master suffers.

I can fully confirm "Observer's" remarks respecting "Cousin Jackey," who appears to be of a more prolific family in London than we often meet with in provincial towns.

ONE WHO KNOWS.

*** Other correspondents make similar statements. We have also received a letter signed "One of Them," denying the correctness of "Observer's" comments, but this can only represent the writer's own experience and practice, and does not affect the charges made. There are, of course, large numbers of foremen acting in the best and most honourable manner. The only question is whether the practices described are carried on to any extent by others, and the letters which have reached us seem to show that they are. Employers should themselves look into the matter.

UNSANITARY BUILDING.

SIR,—At no time does the profession of an architect appear more valuable to the general public, and his services more necessary, than when diseases of a loathsome and dangerous character become rampant. This year small-pox, scarlet fever, typhoid fever, and measles have extensively prevailed, and I cannot help thinking that if the dwellings of the humbler classes and many of the middle classes, were properly constructed, kept in a good and proper state of repair, and clean, according to the best known methods of executing the various branches of work connected with the building trade, there would be very much less disease. But, unfortunately, too much of the work in the building trade is executed without any regard to efficiency or the laws of health, and in the course of time neighbourhoods which have once been known as healthy have become notorious for disease, and many persons have been brought to ruin by the depreciation of the value of their property, and the poorer classes have become pauperised from the want of a better class of inhabitants in the locality to find them the employment necessary for their subsistence. WILLIAM HEY.

THE SMOKE NUISANCE.

SIR,—A prize is offered to free London from smoke; why falter, ye clever ones? This is no joke. Fair play this time, "be on the job"; no filching, no snubbing from official snob. The project is grand; give breath of life; end this unhealthy wasteful strife. The money is little, for small mercies give thanks; compete, men,—the remedy must come from the ranks. This work is ours, right straight in our line; high-salaried incompetents not in it this time.

R. T.

CONDITION OF FAREHAM.

SIR,—I will only ask you to make a short remark. The Fareham Local Board have made no further protest against the statements contained in my second communication which appeared in your issue of the 3rd ult., neither have they replied to the editorial remarks which appeared in the *Hampshire Telegraph*.

I hear on good authority that the Local Government Board have warned the Fareham Local Board that no further loan can be raised by the latter until the closet system is altered. Perhaps the Fareham Local Board are not aware that it has been declared by high legal authority that in such cases of wilfully permitting a public danger to exist they may severally be indicted for manslaughter should fatal results ensue. QUERTOR.

ROMAN VILLA, BRADING.

SIR,—Will you allow me to warn intending visitors to the Roman villa, Brading, that they had better, when paying their money at the turnstile, have an understanding what they may and what they may not see, as they may find themselves curtly shut out of the larger part, while others are admitted, indeed, pressed to go in, under their nose, as happened to me on Thursday last.

I would suggest to the gentlemen who have the matter in hand that if they cannot afford to keep a proper person there, it would be better to leave the whole in the charge of the old man who looks after the older or earlier-discovered portion. A. A. C.

CASE UNDER THE EMPLOYERS' LIABILITY ACT.

FARMAN *v.* JAVENS.

THE plaintiff in this case (which was tried before Mr. Besley, Q.C., in the City of London Court last week, and reported in the *City Press*) was W. Farman, a joiner, residing in Fordham-street, Whitechapel, and the defendant was Mr. J. M. Javens, grocers' fittings manufacturer, Halfmoon-street, Bishopsgate.

Mr. Grain (for the plaintiff) said that on June 29th defendant had completed a sugar shelf, 22 ft. long, 20 in. wide, and 4 in. thick, which was to be lowered from a second story. The ropes were fastened in the usual way, but in letting down the shelf, which was of unusual weight and size, it got caught in a projection from the first floor. His client was ordered by the foreman (named Davey) to go to the floor below and ease the shelf off. He was doing this when the rope was let go by a man named Parrett, who had charge of it, and the shelf swung back, jamming the plaintiff's hand against the rail, which resulted in a serious wound. He went to the hospital and had the wound dressed, but had been incapacitated for work ever since. He claimed 50*l.* damages.

Mr. Fulton (for the defendant) contended that his client had often had similar planks lowered, and there was nothing at all defective in the tackle. He should prove that the blame rested entirely with the plaintiff, who pushed out the plank before another man named Dollard could reach the basement, and Parrett was compelled to let go, which resulted in the accident.

Albert Davey, the foreman, stated that he instructed the plaintiff and Dollard to go below to ease the plank. He did not touch the rope.

John Parrett said he was holding the rope when the plank struck. At first he had the rope fastened, but he had to untie it, as it was too short for him to hold, and when the plank was swung out by plaintiff he was forced to let go.

The judge, in summing up the case, said it was important to give the utmost consideration to claims made by journeymen, as jurymen were supposed to sympathise with the masters rather than with the men—a theory he did not believe. If the jury were of opinion that plaintiff met with the accident while carrying out the instructions of the foreman, and it was owing to the rope held by Parrett being too short for the purpose, they would find a verdict for the plaintiff, but he would not advise them to award the extravagant sum of 50*l.*

The jury gave a verdict for the plaintiff,—damages, 10*l.*

FIRE IN THE MINE.

SIR,—Another mine on fire: the gas, exuding from millions of holes, cracks, and crevices, slowly fills the mine.

How easily and cheaply a remedy could be applied. A small fire-engine to squirt liquefied cement on the roofs and sides liberally; what falls on the ground would bind down the dangerous drifting coal-dust. This coating would prevent falls from the roof and sides by securing them, and every pore would be sealed for ages. R. T.

ASKING FOR WORK.

SIR,—In the *Surrey Advertiser* of September 24th, it is reported that the Clerk of the Guildford Local Board read a letter from Messrs. Gotto & Beesley volunteering their services as consulting engineers at a fee of thirty guineas, and inclosing testimonials. Considering they were not asked, is this quite the right sort of thing? C. E.

CHURCH-BUILDING NEWS.

Llantrissent.—Llantrissent Church, near Usk, has been re-opened, after restoration. The condition of the edifice previously to the recent works was very bad. The nave more particularly bore evidence of damp and dilapidation, and was full of square box pews, old and shabby, and in an exceedingly rotten and worn-out condition. The floors, being uneven and reeking with damp, have been taken up and relaid on solid beds of concrete, after many old vaults were properly repaired and made safe. The whole of the nave roof has had the barrel-plastered ceiling scraped down, and a fine sawn fourteenth-century oak roof exposed to view, the roof being composed of rafters, 6 in. by 6 in. and 18 in. apart from centre to centre, curved and braced. Upon breaking down the plaster barrel ceiling in the chancel, the old axed rafters were found to be so decayed that it was quite dangerous taking them off, and they could not have remained in their position many months longer. These have now been replaced by an open red-pine roof, with principal timbers showing, and the sides framed into panels, with V-jointed boarding, the whole stained and varnished. The square stone tower before the restoration was in a tolerably good state of repair, and, with the exception of pointing and re-setting the battlements on the top, and repairs to bell carriages, this has been untouched. Upon removing old pewing and plaster from the walls of the nave and chancel, an interesting piscina and mural stairs were found. The former has been carefully cleaned and exposed to view, but the latter, owing to some tablets which were not allowed to be removed being fixed in both arches to the same, has again been covered up. All the old stonework to the windows and arches has had the yellowish wash most carefully cleaned off, and the decayed portions made good with new stones, but in no case has any original moulding or splay been altered. The sun-dial was found in the tower, and this has been refixed in its former position over the south porch. The roofs throughout have been covered with Whitland Abbey slates. A new pulpit has been placed on the north side near the chancel arch. The nave has been filled with red pine open seats, with sloping backs, 3 ft. wide, book-boards, &c., these seats being upon a raised floor, with ventilation under the same, all the new woodwork being stained and varnished. The windows have been filled in with coloured cathedral glass, in quarry lights, with marginal borders. The whole of the alterations have been carried out for about 600*l.*, the contract being let to Mr. William Blackburne, builder, of Newport, who has carried out the work from plans prepared by Mr. Lansdowne, architect, of the same town.

High Tointon.—High Tointon Parish Church has been re-opened, after alterations and additions. The interior of the roof, which had been plastered, has been boarded, stained, and varnished. A reredos has also been erected by the vicar's wife in memory of her brother, who died last year at Milan whilst on a tour. It is executed in Ancaster stone, as regards that portion above the level of the Holy table. The lower portion is of red Mansfield stone. The emblems are in mottled Derbyshire alabaster, except the central one, the Agnus Dei, which is of pure white alabaster. In design, the reredos consists (1) of the central feature over the Holy table, which, in order to give it more emphasis, slightly projects beyond the wings, and is of richer character than the latter, and has an ornamental cresting over the cornice. In the centre is a circular panel, its mouldings enriched by pearls carved in the stone, and enclosing a sex-foiled cusped panel with *fleur-de-lis* points, in which stands the Agnus Dei. This panel is flanked by eight circular quatrefoil panels on either side, containing the following sacred emblems:—The Lily, Rose of Sharon, Dove holding Olive-branch, Star of Bethlehem, Passion Flower, Celestial Crown, Wheat, and the Grapes. (2) The wings of the reredos are each divided into three panels, which have square trefoil heads, instead of arched tops, in order to give as much space as possible for the Lord's Prayer, Creed, and Commandments, which are inscribed in legible Gothicised letters on yellow Mansfield stone panels, the lettering being tinted a deep chocolate. Between each panel in the upper part of the reredos is a carved boss in a circular panel. The lower portion of the reredos has been kept plain in design, with lozenge-shaped panels, somewhat having the effect of trellis-work, but to a larger scale. The reredos has been carried out and fixed by Messrs. White & Sons, of Vauxhall Bridge-road, London, from the designs of Mr. B. Edmund Ferrey, architect, London.

Delabole (Cornwall).—A new church, from the designs of Messrs. Hine & Odgers, architects, Plymouth, has recently been consecrated here by the Bishop of Truro. Of Early Geometrical design, it consists of nave, chancel, and south aisle, and seats 300 persons. Situated near to the celebrated slate quarries of Delabole, the walls are of that material, relieved by dressings of granite and Box-ground. The roofs are of steep pitch, and covered with local slate. They are open-timbered, of substantial construction. The chancel roof is enriched by carved angels. The various avenues are of slate, but the chancel floor is of encaustic tiling. The stalls, the lectern, and the chancel fittings are of oak. The font is of Beer stone. It was made by Mr. Harry Hems, of Exeter, who also made the lectern and did the general carving. The windows are glazed with cathedral glass. The contract has been carried out by Messrs. Westlake & Cann, of Camelford.

Plymouth.—Emmanuel Church, at Mannamead, a suburb of Plymouth, has just had a chancel and transepts added to its nave and aisles, which were erected eleven years ago. Messrs. Hine & Odgers, of Plymouth, have carried out the present works. The church is Late Decorated in style, and is well situated upon high ground. Its proportions are lofty. The walling is limestone, the dressings being of Portland and Box-ground. The windows are large, and well filled with tracery. They are glazed with cathedral glass. Mr. W. Morris, of London, is preparing a painted window for the east end, which is a five-light one. The roofs are of steep pitch, covered by slates, and surmounted by high wrought-iron crestings. The roof timbers are of pitch-pine. The chancel roof rests upon sculptured figures of angels in stone. The window labels are stopped by carved heads, and the rough blocks left in the first section have been carved during the present works. Mr. Harry Hems has executed this carving from the architects' designs. The chancel rises three steps from the nave floor. It is laid with Maw's encaustic tiles. The brass gasfittings are by Messrs. Hart, Son, & Peard, of London. The seating generally is of pitch-pine. The chancel stalls are of carved oak and pitch-pine. The pulpit is of oak, and the lectern is of brass. The church is heated by hot air. The builder was Mr. Blowey, of Buckland. The Bishop of Exeter consecrated the church. It is hoped at an early date to erect a south-west spire, 150 ft. high, at a further cost of 1,700*l.*

Birmingham.—The Church of St. Nicolas, Lower Tower-street, Summer-lane, which has been repaired and redecorated, has been re-opened. The church has undergone considerable alteration. New seats of English oak have been placed in the chancel, and the chancel itself has been extended farther into the nave, and enclosed with a low freestone all inlaid with marble panels. A screen, which is of a Gothic design, rests upon this, extend the whole width of the chancel, and rises to a height of about 20 ft. The western screen has been continued across the south aisle. The church has been re-decorated by Messrs. J. R. Lee & Co., of Ann-street. The decorations consist chiefly of bands and pattern-work, stencilled on a greenish-grey ground. The plastering between the rafters of the nave has been finished in a salmon colour, and that between the aisles and chancel-rafters has been coloured a bluish-grey. Texts have been written upon the walls, and the spandrels of the nave arcade and of the windows have been filled in with stencilled pattern work in Indian and Venetian red and black. A painted head of St. Nicolas has been introduced in a circular panel over a recess in the chancel, and the east window has been partly filled in with stained glass, by Messrs. Camm Brothers, the design representing the Crucifixion. The structural alterations have been executed by Messrs. C. Jones & Son, of Belmont-row; and the whole of the work has been carried out from the designs of Mr. John Cotton, architect, of Temple-row.

Knutsford.—The new Church of St. Cross, Knutsford, was consecrated on the 14th ult. It replaces the church built on the same site at the sole expense of the late Mr. Peter Leigh, of Norbury Booths Hall, Knutsford. Though consecrated as lately as February, 1858, it was (according to the *Warrington Guardian*) found necessary in the spring of 1879 to transfer the services to the village school, as the then existing church was pronounced by several firms of architects to be in a most dangerous condition, owing to the breaking of the roof, and the consequent outward thrust of both side walls. The designs of the edifice just erected were prepared by Messrs. Paley & Austin, architects, Lancaster, and the contractor was Mr. Hamilton, of Altrincham. The cost has been 4,000*l.* The building, which is composed of brick and terra cotta, supplied by the Knutsford Brick and Tile Company, consists of nave, transepts, chancel, tower, vestries, and porch. Its total length is 120 ft., being 18 ft. longer than its predecessor. The width of the nave is 23 ft.; of the transept across the nave, 52 ft.; and of the chancel between the side chapel and the organ, 24 ft. The pitch of the roof of the nave is 36 ft. from the floor line; and the tower, 81 ft. in height, is fitted to carry a full peal of bells, with ringers' room, &c. The chancel is separated from the nave by a metal screen, with gates. It contains fifty-five seats for the exclusive use of the choir, with two prayer-desks. The organ-chamber is on the south side of the chancel, and on the north side of the small chapel, which, along with the north transept already mentioned, is used by the children of the school at the morning services. Eastward of the chancel is the sacrarium, with sedilia, credence-table, and the altar, standing under a five-light tracery window, filled in with stained glass. The pews are of pine. The floor of the chancel is laid with ornamental encaustic tiles. Several special gifts have been made to the church. The five-light east window has been filled in with stained glass illustrative of various incidents in the life of Christ, at the sole expense of Major Hill, one of the churchwardens, in remembrance of his parents and sister. The window was furnished

by Mr. Forrest, of Liverpool. An alabaster font, made by Mr. Roddis, of Birmingham, was the gift of Mr. and Mrs. M. M. Speakman, of Knutsford. Mr. W. Jones, J.P., of the Grange, Knutsford, contributed a carved oak pulpit, which rests on a white stone pedestal. The reredos has its central part composed chiefly of wood, carved by Mr. F. Armitage, of Bowden, and given by Mr. B. Gibbons, of Knutsford.

Stourport.—The erection of a new church, from designs prepared by the late Sir Gilbert Scott, at a cost exceeding 30,000*l.*, has been commenced at Stourport. The cost will be principally defrayed through the munificence of the vicar.

Sunderland.—St. Bede's Mission Church has been re-opened, after alterations. The platform which did duty as a pulpit has been removed, and the recess forms a chancel, the window having been filled with painted glass, by Barnett, of Newcastle, the subject being the Good Shepherd. A new pulpit, prayer-desk, and lectern, and an American organ, have been supplied. The exterior has also undergone a change, a belfry having been erected, surmounted with a stone cross. The alterations have been executed under the direction of Mr. M. Greener, architect, Sunderland.

STAINED GLASS.

Halifax.—A two-light stained-glass window has been erected in the north aisle of the old parish church of Halifax by the officers of the 33rd (Duke of Wellington's) Regiment, as a memorial to four of its late officers deceased during service, viz.,—Major A. J. Weeding, Captain E. S. Wason, Lieut. R. S. P. Robinson, and 2nd Lieut. J. B. H. Carmichael, the two last killed by the landslip at Naini Tal, India, September 18th, 1880. The subjects (from Acts x.) are :—(1.) The angel appearing to Cornelius; (2.) Peter visiting and raising the kneeling Cornelius. Each subject group is surmounted by a canopy. The window and tracery are of severe fifteenth-century style. In the bases of the lights are respectively the crests of the Duke of Wellington and of the regiment. A surrounding riband bears the names of the battles inscribed on the regimental flag. The window, by Messrs. Powell Bros., Leeds and London, was erected under the superintendence of Mr. Jackson, architect, Halifax.——In St. John's Wesleyan Chapel, a two-light window, which is dedicated to the memory of Annie, wife of Mr. Henry Edmunds, junior, has just been completed. This window has also issued from the studio of Messrs. Powell Bros. An allegorical figure of "Faith" occupies one light, and another of "Hope" the respondent light. The former is partly supported by a staff, cross crowned (emblematic of the Gospel Word); the latter rests her right hand on the emblem anchor that entereth within the veil. Each stands in front of a shoulder-high white and gold diapered screen, beneath a richly-carved canopy. The ornamented tracery, canopies, and bordures are in fifteenth-century style. The erection of the window was under the superintendence of the architect, Mr. W. Swinden Barber, of Halifax.

Westerdale (Yorkshire).—A two-light window, dedicated to the memory of the late Col. the Hon. Octavius Duncombe, lord of the manor of Westerdale, and for twenty-five years M.P. for the North Riding of the county of York, has been unveiled. The window is in the nave. Each light is divided into two compartments by decorated bordures, allowing of the introduction of four groups, illustrating respectively the Nativity of Christ, his Baptism in Jordan, Crucifixion, and Ascension. The window is from the studio of Messrs. Powell Bros., Leeds, Mr. H. Perkin, of Leeds, being the superintending architect. ——At the same time was unveiled another and smaller painted window, over an entrance-porch, of which the subject is "Christ blessing little Children," dedicated to the memory of two infant children of the Rev. John Rathbone Ellis (the rector), interred at St. Asaph. This window is also by Messrs. Powell Bros.

Edinburgh.—The large central window situated in the south wall of the Preston aisle of St. Giles's Cathedral has been filled with stained glass, the design being illustrative of the life of St. Paul. The window is of large proportions, measuring fully 25 ft. in height by 12 ft. in width, and consists of ten compartments, in addition to the flowing tracery above. The two conspicuous events in the life of St. Paul are depicted,—his Conversion on the way to Damascus, and his Preaching at Athens. The upper panels are devoted to the former, and the lower panels to the latter. The whole work has been designed and executed by Messrs. Ballantine, under the honorary superintendence of Mr. Robert Herdman, R.S.A., and the St. Giles's Restoration Committee. The window is the eleventh of the series of completed windows. The memorial is inscribed, "In memory of Duncan Monteith, merchant, Calcutta, born at Thornhill, 1812; died at Edinburgh, 1879; erected by his daughters, Margaret, Agnes, and Sibla, 1881."

London.—A window of painted glass has just been erected from the design of Mr. Burne Jones in St. Peter's Church, Vere-street, Oxford-street. It occupies the whole east end of the chancel. The central group represents our Saviour conversing with the woman of Samaria.

Newbury.—The new window which has been provided from the funds of the St. Nicholas Stained-glass Window Society, and which is one of a series it is proposed to insert, has been filled in in the south aisle of the parish church, by Messrs. Hardman & Co., of Birmingham. It consists of four lights and tracery. The subjects chosen for illustration are taken from the parables of our Lord. In the first or dexter light is depicted the parable of the Pharisee and the Publican; in the two middle lights that of the Wise and Foolish Virgins; and in the fourth or sinister light the Return of the Prodigal Son.

Kidderminster.—A stained-glass window has been placed in the north transept of St. John's Church, Kiddermiuster, by Mr. W. J. Wyley, in memory of the late Mr. Joseph Kitley. It is a three-light window, and represents scenes in the life of Daniel, the prophet. In the first light Daniel is represented as interpreting the King's dream; in the second he is occupying the position of the president of the council; and in the third he is on his knees, praying. The window has been supplied by Mr. John Davies, Wyle Cop, Shrewsbury.

Miscellanea.

Proceedings at the Clerkenwell Vestry.—At the last meeting of the Clerkenwell Vestry, held on the 23rd ult., two hours were spent in a somewhat acrimonious discussion arising out of a motion for the acceptance of a tender, amounting to 48*l.*, for some carpenters' work. The motion was to the effect that the tender should be accepted "on condition that no commission be paid to Mr. ——"(one of the Vestrymen being named). The member referred to made an explanation denying that he had ever received commission from contractors on work done for the Vestry, and ultimately the subject was referred to a committee of the whole Board. The next business was the appointment of an assistant in the Surveyor's office. Six candidates had been chosen by a committee deputed to examine their drawings, testimonials, &c., and these candidates duly appeared at the vestry meeting, expecting that one of them would be elected to fill the vacancy. But, we are informed, nothing of the sort took place. The assembled vestrymen voted for a candidate not included among the six recommended by the committee. As soon as the voting was over, a member asked whether it was true that the chosen candidate had been introduced to many vestrymen by the Surveyor during the week? This query was met by cries of "Too late!" Nevertheless, some explanation appears to be needed.

An Abstracted Picture.—A mysterious affair, recalling the strange disappearance of the Gainsborough picture some years ago, is now being investigated by the Scotland-yard authorities. The picture known as the "Monarch of the Meadows," painted by Mr. T. Sydney Cooper, R.A., and the property of Mr. Allcroft, M.P., of Lancaster-gate, Hyde Park, has been destroyed or stolen. On the morning of the 13th inst. a room in Mr. Allcroft's house, in which the picture was standing during the general repair of the building, was discovered to be in flames. The Fire Brigade were at once summoned, and the fire was rapidly got under. On examination it was found that the picture had been cut out of the frame either before or after the fire had commenced. The police were at once communicated with, and the most searching investigation is being made into the matter. The surprising part of the affair is the fact that no traces are to be found of an entrance to the house having been obtained. The painting was valued at 5,000*l.*

Hull and Barnsley Railway.—The works of the dock in course of construction in connexion with this line have made great progress during the last few weeks. The river embankment is being rapidly raised, and in some parts is only 5 ft. below high-water mark. As many as fifty cargoes of chalk are discharged every week. A great part of this material is brought from the quarry of Messrs. Lucas & Aird, at Barton; but the progress made is so rapid that at present they find their own quarry will not supply all the chalk required, and much is also obtained from other sources. A large cofferdam which will contain about 1,500 piles, and which is being constructed in front of the entrance, is being pushed with all vigour. Preparations are being made for continuous work, night and day, and in a few days there will be two powerful electric lights in use, and these will enable the work to proceed continuously. A powerful double dredger is at work removing the Hebbles Shoal from the entrance, and the material dredged is carried in iron hopper barges behind the chalk embankment, and assists in filling up the quays. The concrete foundations of the north wall of the dock are being laid, and upwards of 150,000 cubic feet of stone have been deposited on the work, so that, when once commenced, the masonry of the dock-walls will progress without any delay whatever. It is expected that the foundations will be ready, and the first stone laid, in a few weeks. The stone is all brought from the fine quarries near Leeds and Harrogate, and is of the hardest description. All the bridges are now built between Spring-bank and the Beverley-road, so there will be nothing to delay the progress of the embankment. The bridge over the Beverley-road will be commenced almost immediately on the east side of the river Hull. A start has been made on the bridge and viaduct over the Sutton Drain.—*Engineer.*

The Retabulum in Westminster Abbey.—"H. P." writes to *Notes and Queries*:—"Who was the first discoverer of the retabulum which is now exhibited at the back of the sedilia in Westminster Abbey? I forestall this query, to which, otherwise, your valuable columns would at some future day be subject. I also forestall the reply, because I think I have the true one, and because I think it ought not to be delayed." He goes on to show that the credit has been given to the late Mr. Blore, on the strength of a printed paper left by Mr. Willement, and then continues,—"I have lately come across another paper on the same subject, dated thirty-four years before that of Mr. Willement. This paper is dated July 19, 1817; it is by Mr. John Carter, F.S.A., draughtsman and architect, a frequent contributor to the *Gentleman's Magazine*. This paper was the last but one that he wrote, for he died, aged sixty-nine, on the 8th of the following September. After commending the waxen portrait and dress of King Charles II.'s effigy, he says:—

"In a box inclosing other Royal wax figures in Islip's chantry, has been substituted, by way of covering, some compartmented work of small mosaic ornamental carvings and paintings of figures, of a design so delicate, an execution so exquisite, that an absolute view alone of the same, and that with the utmost attention, can give the least idea thereof. No hesitation need be made, when it is affirmed, that it must have been a small portion of the highly estimated shrines that once rendered the scenic display of the interior of the pile so shining and glorious!"

Messrs. Thomas & Sons' Lifts.—Sir E. J. Reed, M.P., has been visiting Cardiff to inspect the Exhibition there. After leaving the Drill-hall, the member for the united boroughs proceeded to the Acme Hoist Works, Penarth-road, recently erected by Messrs. Thomas & Sons. He made a survey of the works, but was more especially interested in the specialities which were shown to him in self-sustaining hoisting machinery. Of these he spoke in terms of approval, foretelling to Messrs. Thomas & Sons a bright future for their new arrangements in a useful branch of engineering.

Cheap Literature. — The publication by Messrs. Longmans, Green, & Co., of Lady Brassey's bright, breezy, and popular "Voyage in the Sunbeam" at the price of *sixpence* marks the commencement of an era. It is clearly printed and fully illustrated, and will doubtless penetrate far and wide throughout the kingdom, to be read with pleasure and profit by all classes.

Stamford Priory.—Mr. C. Kains-Jackson writes to say that the threatened desecration of Stamford Priory has been definitely averted, the scheme of turning it into a cart hovel being altogether abandoned.

"The Caravanserai."—Mr. Alsager H. Hill sends us the prospectus of what, as it seems to us, might be made a useful institution. The proposal is to establish in London, in direct connexion with the Central Labour Exchange, "The Caravanserai and Travellers' Rest." The situation selected will be as central as can be secured. At the present time large numbers of workmen, more especially those fresh from the country, find no immediate resort but the common lodging-house, with no facilities for obtaining the necessary information and guidance in their search for work. Apart from the sleeping accommodation, which will be at least equal to the best afforded by the ordinary lodging-house, the "Caravanserai" will, as a special feature, through a reading-room and Labour Exchange attached thereto, supply all the leading facts of the labour market from day to day, and arrangements will be made for employers forwarding to the establishment any special or sudden demand for hands. For the intending emigrant as well as to the stranger settling in London, special information will also be afforded under the auspices of the Central Emigration Agency. The establishment will be on a strictly commercial basis, and only such rules as are necessary to insure discipline and good order will be enforced on the premises. Every facility will be given for employer and employed to meet on the premises. We understand there is something of the kind at Leeds which works well.

Fall of a Church Tower.—The old tower of the church of St. Helen, at the village of West Keal, near Spilsby, Lincolnshire, fell with a crash on Sunday, the 18th ult. Shortly before eleven o'clock, the rector, the Rev. J. S. Ladds, while in the edifice, before the commencement of the morning service, was alarmed by some portions of stonework falling, and ominous sounds proceeding from the tower. Quitting the edifice, others were warned of the approaching danger, and not long afrer the tower showed widened clefts or breaches in its walls, visibly shook, tottered, and fell *en masse*, but, fortunately, without hurt to any one. Nearly the whole of the tower fell to the south in the churchyard, clear of the edifice, with some portions bulging off north and west. The tower was built principally of sandstone, and was one of the most ancient in the neighbourhood. Latterly, from its patched appearance, with brickwork, &c., from repeated repairs, it has presented a very unstable appearance, and ugly fissures were apparent in its walls. The *Lincolnshire Chronicle* says that the heap of ruins show the tower to have fallen from thorough natural decay. The church itself was new roofed in 1853, re-seated in 1865, and the chancel rebuilt in 1867, together with its quaint stone-roofed porch, which is still standing.

A Monster Crane.—One of the largest cranes of its kind has just been manufactured for Mr. J. Dickinson, Sunderland, intended for the Quayside. Messrs. F. & J. Butterfield, Keighley, are the manufacturers of the crane, which will cost, including fixing, about 30,000*l*. It is constructed of wrought iron, mounted on four carriages, each having four runners 3 ft. in diameter. A cast-iron wheel rack is fixed in the centre of the foundation, 25 ft. in diameter, a circular-rack 6¼ pitch being fixed upon it for moving the crane. The length of the jib is 71 ft., and it has a lift of 90 ft., with a staging on the top for a man to stand on. The chain is passed over wrought-iron capped drums, 14¾ in. diameter, milled out to suit the chain, which is 1⅜ in. diameter, five teeth to fit into the links of the chain being fixed on the drum. The crane is geared for twelve, twenty-five, and fifty tons respectively.

Circumlocution in India.—The *Bombay Gazette* says that if a chimney smokes in a barrack at Rangoon the difficulty is encountered as follows:—The officer commanding the troops who occupy the building refers the matter to the proper staff officer, whoever he may be; he communicates with the military staff at Madras; and the commander-in-chief of that Presidency brings the question to the notice of the local Government. The Government of Madras then addresses the Government of India at Simla, and the papers on the subject travel about that pleasant station for a while in boxes. There a despatch is prepared, and finally sent to the Chief Commissioner of British Burmah, who sets the machinery of his administration in motion, and then the officer in charge of military works at Rangoon sends for a mistree, and the chimney is set to rights.

University College, Bristol.—The calendar for the sixth session of University College, Bristol, has just been received. It shows a course of lectures extending over all, or nearly all, the chief branches of a liberal and scientific education. Special attention has been paid to the chemical and engineering departments. Each of them in its own way combines theoretical with practical instruction. In the former, laboratory work, both in the day and evening, supplements the instruction given by general and technical lectures. And in connexion with the latter, arrangements are made by which students attend lectures at the College during the six winter months of the year, and gain their practical experience during the summer months, when they work as articled pupils in the offices and workshops of leading engineering firms of the neighbourhood. The instruction in experimental physics is kept abreast of the rapidly-increasing requirements of the age; and in this subject, as well as in geology, special provision is made for the wants of the engineering students. The growth of Bristol in moral, mental, and material wealth must be much promoted by an institution which gives, as this does, instruction to over 500 men and women. It is to be regretted that the College has no foundation.

Proposed Theatre for Yokohama.—An endeavour is being made to provide Yokohama with a new theatre and public hall. It is proposed, according to the *Japan Weekly Mail*, to start a Public Hall Company, with a capital of $20,000, in 400 shares of $50 each. An active Provisional Committee (composed of Messrs. Ahrens, Bridgford, Emory, Enslie, Fitz-Henry, Fobes, Griffin, Herbert, Rice, and Townley) has been for some time at work over the preliminaries, and it is believed that their efforts to float the scheme will be crowned with success. The Choral and Dramatic Societies have subscribed the sum of $1,000. It is calculated that a building capable of holding 500 persons can be erected in brick and iron, with all internal fittings and furniture complete, for $15,000. Including the purchase of a suitable plot of ground, the sum of $20,000 will be ample for all purposes.

Art at Cardiff.—The fine-art and industrial exhibition at Cardiff, which has been open for the past two months, and has been visited by some 120,000 persons, was brought to a close on Wednesday last. By this exhibition about 3,000*l*. has been raised towards the furnishing and decoration of the local museum and science and art schools and the formation of an art gallery in the town. Sir E. J. Reed, who attended a dinner given to the executive committee of the exhibition a few days ago, then and there presented, as a contribution to the art gallery, Vicat Cole's landscape entitled "Noon," which, while on loan in the exhibition just closed, has been greatly admired by the visitors. The Mayor, in acknowledging this handsome gift, said that its value was 1,000 guineas. It was exhibited at the Royal Academy in 1873.

Congregational Chapel Building.—The builders in the metropolis, according to our contemporary, the *City Press*, have a bright prospect before them so far as regards the erection of places of public worship, seeing that the Congregationalists estimate that they must build eighteen chapels yearly, each capable of holding 1,000 people, even to maintain their present position proportionately to the population. Most other denominations have doubtless to face the same problem, and as some of them have in addition leeway to make up, the erection of new ecclesiastical edifices in London promises to continue.

The Building Trades in Melbourne.—The Melbourne correspondent of the *Times*, writing on August 15th, says,—"A very large number of houses are now in course of erection in Melbourne and the suburbs, and no artisan connected with the building trades need be out of employ if able and willing to work. The demand for bricks so exceeds the supply that orders remain unexecuted for weeks."

Brighton Sanitary Exhibition.—The executive committee have decided to hold a health congress in connexion with the projected sanitary and scientific exhibition at Brighton in December next. The Pavilion committee resolved on Monday to recommend the Town Council to grant the promoters the free use of the whole of the Pavilion buildings.

A Fine-Art Exhibition at Leicester has been opened this week. The pictures number 256.

Open Areas in the Rear of Dwelling-houses in the Metropolis.—At the last meeting of the Lambeth Vestry, Mr. Symons inquired whether it was intended by the Metropolitan Board of Works to obtain an alteration in the Building Act, so as to prevent the backs of houses being built so close together. He also wished to know whether Mr. Fowler, a representative of the Vestry at the Board, would direct the attention of the board to the alleged failure of justice in the case of houses being commenced before action could be taken to prevent their erection. In reply, Mr. Fowler said the Building Act Committee of the Metropolitan Board had before them a book in which anything which appeared to require emendation in the Act was entered. These alterations would no doubt be included—certainly the important question of increasing the area at the backs of houses.

Ecclesiastical Art Exhibition, Newcastle-on-Tyne—Concurrently with the Church Congress at Newcastle-on-Tyne there will be opened on Monday, the 3rd of October, an Exhibition of Ecclesiastical Art, under the same management as in previous years. The Exhibition will be held at the Auction Rooms, Pilgrim-street. Most of the leading church furnishers are exhibitors, and there is, in addition, a loan collection. Perhaps no one single subject is so thoroughly illustrated as that embraced by Mr. Bragge's collection of 124 Russo-Greek "Icons," or religious pictures, which are so frequently met with in Russia.

The New Corn Exchange Buildings in Sheffield, which cover an area of about 1,500 square yards, and which are now on the eve of completion, were inspected on the 26th ult. by the proprietor, the Duke of Norfolk, lord of the manor. Messrs. Hadfield & Son are the architects. We shall illustrate the new buildings fully before long.

Election of Borough Engineer for Leeds.—A special meeting of the Leeds town council was held on the 22nd ult. for the purpose of appointing a borough engineer, at a salary of 600*l*. a year. There were eighty applications for the post, which has been conferred upon Mr. Thomas Hewson, borough surveyor of Rochdale.

Adelaide Exhibition.—We hear with pleasure that "the gold medal of the Adelaide Exhibition has been awarded to Mr. George Jennings,"—we conclude, for his various important improvements in sanitary appliances and his inventions.

Charing-cross Hospital.—The new school buildings here are to be the scene of a *conversazione* on Monday, the 3rd. Invitations have been sent out by the medical officers and lecturers.

TENDERS

For the erection of additional schools, &c., for the accommodation of about 500 children, in the Banstead-road, Sutton, Surrey, for the Managers of the South Metropolitan School District. Mr. William Wallen, architect. Quantities by Messrs. Franklin & Andrews:—

W. D. Macgregor, London	£109,815 0 0
Jno. Tyerman, London	95,289 0 0
Albert Kimberley, Banbury	94,276 0 0
D. C. Jones & Co., Gloucester	92,817 0 0
Wm. Shepherd, London	91,650 0 0
Fred. Higgs, London	90,750 0 0
Wm. Saurmur, London	88,904 0 0
Jno. Mowlem & Co., London	85,857 0 0
Higgs & Hill, London	85,844 0 0
T. Rider & Son, London	84,888 0 0
Wm. Tongue, London	84,255 0 0
Perry & Co., London	83,949 0 0
Jno. T. Chappell, London	83,809 0 0
C. E. Nightingale, London	83,383 0 0
Jas. Longley, Worth, Sussex	83,846 0 0
W. J. Adcock, Dover	82,704 0 0
W. Crockett, Epsom	82,695 0 0
Jno. Marsland, London	82,473 0 0
T. Boyce, London	82,443 0 0
Paramor & Son, Margate	82,350 0 0
Geo. Shaw, London	81,510 0 0

Long	1,281 10 6
Green (accepted)	1,256 0 0 !

For the erection of a pair of semi-detached residences, on the Eston-road, Coventry, for Messrs. Beamish & Loudon. Mr. William Tomlinson, architect:—

G. J. & J. Fox, Atherstone	£3,693 0 0
J. Worwood, Coventry	3,289 0 0
H. Price, Coventry	3,222 0 0
Hallam & Co., Coventry	2,950 0 0
Smith & Son, Kenilworth	2 840 0 0
Chas. Haywood, jun., Coventry *	2,575 0 0
Jos. Makepeace, Coventry	2,550 0 0

* Accepted for slightly revised scheme.

For veterinary stabling, &c., Nottingham, for Mr. J. P. Ford. Messrs. S. Dutton Walker & Howitt, architects:—

Messrs.	£481 0 0
Jelley	479 0 0
Bell & Son	466 0 0
Clarke	461 0 0
Vickers	447 0 0
Lynam	434 0 0
Scott, Nottingham (accepted)	417 0 0

For rebuilding the Old Red Lion, Hammersmith Mall. Mr. W. Nunn, architect:—

Hunt	£1,180 0 0
Lamble	1,165 0 0
Eyles	1,159 0 0
Wescombe	1,142 0 0
Mansell	1,130 0 0
Chamberlain	1,119 0 0
Nye	1,045 0 0

For Halsey Villas, Woodford. Mr. E. Egan, architect:—

Masters	£1,507 0 0
Egan	1,488 0 0
Wells	1,457 0 0
North, Bros.	1,450 0 0
Reed	1,440 0 0
Wood	1,425 0 0

For pair of villa residences, Hillside, St. Albans, for Mr. Wells. Messrs. J. & F. Clarkson, architects:—

J. S. King, Hornsey	£2,350 0 0
Staines & Sons	2,234 0 0
Savage	1,993 0 0
White, Dunstable	1,990 0 0
Capper	1,690 0 0
Ede & Son, St. Neot's	1,561 0 0
Shoal & Co.	1,555 0 0

For the erection of a detached residence on the Whitgift Estate, Addiscombe. Mr. Daniel R. Dale, architect:—

Marriage, Croydon	£2,820 0 0
Hoare & Son, Blackfriars-road *	2,631 0 0

* Accepted subject to certain alterations.

For a pair of semi-detached villas, at Potters' Bar, for Mr. Ernest Tabernacle. Mr. Burton C. Ravenscroft, architect:—

Eldridge & Gee (accepted).

For internal decorations and repairs at Lensdale House, Poynder's-road, Clapham Park, for Mr. Thomas Fall:—

T. Potterton (accepted).

For the erection of a pair of model cottages on the Essex Estate, Pentlow, Essex, for the Society for the Propagation of the Gospel:—

Geo. Grimwood & Sons, Sudbury (accepted).

The New Egyptian Rooms in the British Museum.

THE removal of the splendid collections of mineralogical and palæontological specimens from the British Museum buildings at Bloomsbury to the new edifice which is designated the "British Museum (Natural History)" at South Kensington, liberated a large superficies of floor and wall space at the former building. This enabled the authorities at once to take steps for the commencement of the new system of arrangement of antiquities which, when complete, will comprehend not only all the antiquarian relics in the Museum, but those also which are still preserved at the Christy Museum in Victoria-street. The whole of the northern gallery has thus been apportioned to new undertakings. The Egyptian and Assyrian studies are now placed more commodiously at the north-west corners; then comes a room, which formerly held the palæontological relics, now devoted to a display of Etruscan sarcophagi, terra-cottas, and fictilia, of which we hope to give an account at some future time; then more to the eastward, two large rooms, filled with the collection of the smaller Egyptian objects; these rooms are bounded to the east by temporary zoological studies, and at the extreme eastern corner by a refreshment-room. The larger and heavier objects of Egyptian history and art, that is, the stone remains and some cases of statuettes and architectural fragments, remain in the Egyptian gallery on the ground floor.

It is of the contents of these two new Egyptian rooms in the northern gallery that it is proposed to point out, on the present occasion, some of the salient points of arrangement and intrinsic interest. These Egyptian antiquities have been principally acquired from collectors or by purchases at public sales. The principal of these acquisitions are the collection of the well-known traveller, Mr. Salt, purchased by the trustees in 1821; a smaller collection of choice objects presented by the late Sir J. Gardner Wilkinson, in 1834; purchases selected at the sale of the Barker collection in 1835, and of the Sams' collection in the same year; the sale of the objects brought to England by the equally celebrated African traveller, Mr. Burton, in 1836; of Signor Anastasi in 1839, and again in 1857; of the Oriental writer, Mr. Lane, in 1842, and of the Earl of Belmore in 1843; a selection of the extensive Hay collection, gathered by Mr. Robert Hay, of Linplum, N.B., during his private but important expedition to Egypt and Nubia, about the year 1826, in company with several artists and antiquaries; and numerous antiquities of a very miscellaneous but not less valuable character purchased and presented by the Rev. Greville Chester, a not unfrequent sojourner in the land watered by the Nile.

In the arrangement of the two rooms which hold all these invaluable relics an instructive classification has been adopted. The first or westernmost room, which is entered by the visitor by turning to the left, immediately on reaching the head of the north-east staircase, situate at the end of the Egyptian gallery on the ground-floor, comprises objects of religious, military, and domestic life, while the second, or inner room, more to the eastward, is devoted to the vast number of relics connected with the dead. Thus we are enabled to see, almost at a glance, the two great phases of evolution which Egyptian art embraced,—national products and necessities of a progressing civilisation in the one room, the bias of funereal *cultus*, and the whole sepulchral art in the other. Great diversity of opinion still prevails, and we fear is likely to prevail, on the subject of Egyptian chronology; indeed, to so impracticable a deadlock have the lucubrations of some writers reduced the chronology of Egyptian history that the most prominent Egyptologists, both in England and abroad, have abandoned this branch of study to lecturers and dilettanti, and directed their attention more to the elucidation of the philological aspects of the language and literature, and to the decipherment of inscriptions and papyri, than to the strict arrangement of reigns, and to the confused pedigrees of the ancient members of the dynastic families. Hence, throughout the collection in the British Museum, wisely, no attempt is made to assign the older objects to a fixed date, but only to the intervals of time marked by the dynasties which successively reigned over Egypt. The locality, however, from which the individual objects come, has been indicated, if known, upon a descriptive label.

Taking the cases in the first room, in order of their numeration, Nos. 1–12 are filled with the objects of the Pantheon or Religious World,—sacred figures of gods and animals. In this section the silver and bronze objects are principally votive offerings which have been attached to the walls of temples and found under the pavements; the hard stone objects are either pendants of necklaces,—a favourite personal ornament with the race,—or small votive figures; the porcelain objects come from the networks with which mummies have been enveloped, or from necklaces clasped around the necks of the departed, these being selected and incorporated into the Pantheon without reference to the purpose to which they were applied, but simply as illustrating the religious cult of the nation. The religions consisted of an extensive polytheism represented by a series of local triad groups. The idea of a single deity, self-existing or self-produced, was involved in the conception of some of the principal gods who are said to have given birth to or produced inferior gods, men, all beings, and all things. Some of the deities were considered to be self-produced. The Sun was the older object of worship, here, as in many other countries; and, as the rising, midday, or setting orb, was invested with different names and propitiated with varying forms of reverence. But the oldest of all the local deities was the Memphian Ptah, the demiurgos or creator of the heavens, earth, gods, and men, and not identified with the sun. Besides the worship of the solar gods, that of Osiris prevailed extensively, and with it, the antagonism of Set, the Egyptian Satan; and the tenets of a transmigration of the soul, a future judgment, purgatory or Hades, the *karneter* or hall of the gods, the *Aahlu*, or elysian fields, and final reunion of soul to body after the lapse of æons, all find illustration in the objects of this class. And, as in other mythological systems, besides the deities of heaven, the light, and the lower world, other inferior personages presided over the elements and operations of nature, the seasons, and events. Most, however, of the important gods were solar, representing various epochs in the path of that luminary either above or below the earth. It is interesting also to note the triadic grouping of deities according to their locality. Thus, at Memphis the triad consisted of Ptah, his consort Merienptah, and their son Nefer Tam; at Abydos, Osiris, Isis, and Horus, with Nephthys sometimes added; at Thebes, Amen-Ra or Ammon, Mut, and Chons, with Neith occasionally added, and so on. When these religions grew debased from admixture of foreign myths, Bel or Baal, Astarte, Ken, and Respu, were adopted from Semitic sources. At this later time, too, a triple classification of gods seems to have been admitted. Some of the types of the Pantheon are wanting, and some are exceedingly rare; but the British Museum collection will contrast favourably with those at Paris, Berlin, Turin, Boulaq, and other national museums. The nature of the material used for different deities is very instructive: thus Osiris is usually in bronze, very rarely in porcelain; Shu, the Egyptian Hercules, and Taur, the wife of Typhon, a mystical goddess, composed of the hippopotamus, crocodile, and lion, are, on the other hand, rarely, if ever, found in bronze. The silver figure of Amen-Ra, as a man, walking, and formerly covered with thick gold leaf,—a Theban relic,—is of great value and rarity; the golden figure of Chons, seated with the moon's disk on his head, and the golden Athor, the celestial mother, with the sun's disk, another Theban treasure, are worthy of especial admiration in this class. The bronzes are very numerous, and there are four interesting porcelain figures of "Ptah-Socharis-Osiris,"

the Pataikos of Memphis according to Herodotus. Another rare object is a figure of Isis, in gilded bronze, the goddess being represented seated in the act of giving suck to the infant Horus, whose figure is broken off. This goddess was the wife of Osiris, and her soul was believed to be enshrined in Sothis, the Dog-star, the heliacal rising of which played an important part in the Egyptian calendar.

Case 13 contains a number of votive statues and statnettes; the smaller objects have rings by which they were suspended to walls of temples. Many of these, no doubt, were intended to represent portraits of defunct persons, in the costume and style of the class or period to which they belonged. Carved wooden figures of considerable artistic merit have been found belonging to a period as old as the fourth dynasty. On the pedestals are dedications to different deities. The woods used were ebony, cedar, acacia, and sycamore, the first-mentioned being harder and more costly; the commoner examples are coloured to hide the coarseness of the grain. No. 14 has a selection of objects of furniture, which in the Egyptian household consisted chiefly of richly inlaid bedsteads or couches, wooden head-rests, foot-stools, tables, chairs, and boxes. For inlaying, ivory, glass-pastes, parquetry, and other vehicles were employed; feather cushions, panther-skins, mats of fibre, and other light furniture supplied the wants of the Egyptian householder. The next twelve cases, Nos. 15-26, contain principally vases of different forms, and made of various materials. Stone of several sorts was used for making bowls, jugs, and other forms destined to hold the liquid or solid offerings to the gods or otherwise employed for religious or domestic purposes. Granite, basalt, serpentine, and alabaster or arragonite, a kind of stalagmite of a creamy white colour of great beauty, opaque and occasionally zoned or banded, were favourite substances, and there are many choice examples of these in the national collection. On many alabaster vases is inscribed the name of the monarch in whose reign they were made, as well as of the person in whose tomb they were deposited, and even the measure of their capacity or their dedication to sepulchral uses. These alabaster vases were highly prized, and used for domestic purposes by the richer classes alone. They were even exported from Egypt, and the names of Persian monarchs are found in hieroglyphics upon them. Asia Minor, Greece, and the Isles of the Archipelago occasionally yield, to the explorer of tombs of early date, vases of Egyptian material, if not of Egyptian manufacture. Nos. 27 and 28 contain bronze vessels, and food, fruits, and seeds. The use of bronze vases from the earliest time is sufficiently demonstrated by the discovery of statuettes, weapons, and vessels, with inscriptions upon them, as old as the sixth Egyptian dynasty, that is, about two thousand years before Christ, according to one school of historians, or nearly four thousand according to another school. The shapes are various: jugs, ewers with long spouts, washing-basins in form of the flower of a water-plant, small jugs, cauldrons with two rings holding a loose-looped handle like a modern pail, *situlæ* or buckets, and drinking-vessels of many patterns, occur in this division. They are, as a general rule, remarkably well made, and in good preservation, the material in this respect being very durable. In this division there is also a bronze votive table, or model, inscribed with the name of a priest; upon it are several small model figures of ewers, basins, jugs, plates, and a colander. This is attributed, in point of date, to the remote period of the sixth dynasty, a time of which, curiously enough, there are more memorials preserved in European museums than of succeeding dynasties. As to food substances, Sir Gardner Wilkinson, who has done more than any one else to illustrate the manners and customs of Egyptian life, discusses this branch of his subject at considerable length. Oxen, calves, goats, antelopes, the ibex and leucoryx, and even hyena, were eaten. The sheep, however, is not found. Equally remarkable, too, is the absence of the domestic fowl from the list of birds used at table, while we find various kinds of water-fowl, geese, ducks, cranes, and pigeons commonly in use. The various species of Nile fish, forbidden to, or rather rejected by, the priests as unclean, were, notwithstanding, eaten by some, and either salted or preserved, or eaten fresh. Of these viands, few remains of meat have been discovered, but in the Museum collection are several specimens of bread, fruits, seeds, fish, and a duck prepared for eating, placed upon a small stand. Of the fruit and seeds, we have cakes of barley bread, sometimes in fancy shapes like modern pastry, grapes, figs, dates, pomegranates, olives, cucumbers, onions, and the esculent root of papyrus. Milk, wine, and beer also formed items of the Egyptian commissariat, and some of the wall-paintings of the Theban tombs,—reproduced in many illustrated works on Egyptian manners,—testify to the way in which drinking to excess was practised at the banquet.

The next case, 29, contains arms and implements, weapons and staves, or walking-sticks. The cultivation of the land was carried on by the plough, hoe, and wooden pickaxe, water for the important necessity of irrigation being raised from a well by a long pole on a pivot, or in jars. The use of the sickle also is found. Among the objects in this division are wooden hoes and pickaxes, an iron sickle from Thebes, and a yoke for the carriage of water-buckets. The stick or wand was carried by private persons, and with a short stick the punishment of the bastinado was administered to culprits; several of these, in wood, ebony, bronze, and other materials, are in this division. There is also the head of a papyrus sceptre or stick, composed of felspar. The principal weapons are the bow and arrow, the war-axe, the mace or club, and the short sword or dagger. For defence, the shield of leather, breast-plates armed with metal scales, and hardened crocodile-hide. The cutting edges of weapons are of bronze, the use of which appeared first in Egypt in the time of Psammetichus I., when the Carians and others, allies and mercenaries, first came to Egypt with such armour; and it is doubtful if the use of iron was known in Egypt at an early period. But the natives must have had some method of so hardening their bronze (which contains about 94 parts copper, 5·9 tin, 0·1 iron) that they were enabled to cut and smooth some of the hardest kinds of granite, porphyry, and other rocks and stone. Fishing implements, such as bronze harpoon-heads, wooden boomerangs, or throwing sticks, used with deadly precision against the waterfowl in the papyrus thickets; and instruments for writing and painting, follow next in order. In these cases, among other fine objects, attention may be drawn to a bronze knife, with a handle of onyx; daggers, with handles of gold, silver, ivory, and bronze; cakes of painters' colours; palettes, with various inscriptions; and a leather bag holding razors. Writing materials consisted of the palette; inkstands of alabaster, with oval or cartouche-shaped depressions or wells for red and black ink, for the titles of chapters in the papyri were written in red ink, as in our own Mediæval manuscripts; reeds for writing; and small cups or vases to contain pigments. The principal colours employed to illustrate writings, or to ornament small objects, are red and yellow ochre, blue and green tints of oxides of copper, white plaster, and animal or bone black, suspended in a gum, probably the common gum-arabic. Painters' slabs and mullers are by no means uncommon.

We will complete the account in our next.

ST. SOPHIA.

In more than one respect the great church founded by Justinian at Constantinople upwards of thirteen centuries ago may be considered to be one of the most typical buildings in the world. Regarded from a purely architectural point of view, it is the great example of the domed style, the finest of all styles for interior effect, carried out in a complete and homogeneous manner. It is also the most marked illustration of the employment of architecture purely as a source of interior effect. In this respect, in regard to the degree in which exterior and interior effect respectively, has been consulted, the leading architectural styles of the world are very various in their principle and practice. In some, internal and external effect seem to be about equally balanced, as in the Mediæval cathedrals. In some great buildings, such as St. Peter's, there is practically a failure in effect externally which was not intended, which resulted from the mistakes of some of the architects concerned. In modern Western architecture we not unfrequently find the whole of the architectural effect external, and the interior of the building merely arranged for practical purposes, as in many of our town-halls and municipal buildings. This extreme is the one peculiar to Western architecture, as the opposite extreme is peculiar to Eastern architecture. In the domestic architecture of the East, we find that dwellings of the richest and most sumptuous decoration internally present not a feature externally, a fact which has been sometimes taken as indicative of the social selfishness and isolation of Eastern life. But the great church at Constantinople stands as a solitary example of the erection of a building on the largest scale and of the most magnificent internal effect, in which external architecture is absolutely wanting, and no attempt seems to have been made to render the exterior anything beyond a rough shell to protect the precious kernel of the interior. Even the evidence of design arising from good construction is wanting. Immense masses of matter have been piled up outside in what, even from an engineering point of view must be called the rudest manner, to hold up by their sheer weight and *vis inertiæ* the beautiful internal construction,—masses which are absolutely unsightly, and the work of which might have been done by half the materials scientifically arranged, and of course with infinitely better effect. Yet, entering within this misshapen mass, we find one of the most complete pieces of masonic construction, and one of the most effective and gorgeous interiors, which architecture has ever produced, and we may look all over the world without finding any other example of such a contrast between the outward promise and the interior result. In another respect, too, St. Sophia occupies an exceptional position, as the chief link between the Classic and the Gothic schools in regard to architectural detail, the centre from which radiated the beautiful types of carved ornament, in the shape more especially of capitals, which were to be modified and worked out in France into the more delicate and logical forms of the complete Gothic capital. In this respect the influence of St. Sophia has differed very much in regard to general design as compared with detail. In general design, internally, it was the culmination, the complete working-out of the domical system first suggested by the Romans; and hardly anything so complete in this respect has been achieved since. In detail, on the other hand, it was still tentative, and was a *point de départ* rather than a culmination. To add to its other points of singular interest, St. Sophia has had the remarkable fate of having been built for the celebration of the most characteristic and strongly defined form of Christian ritual, and of having been transformed into the principal home of the ritual of the strongest and most uncompromising rival of the Christian religion.

It is a question to be asked, in regard to the extraordinary discrepancy between the exterior and interior effects of St. Sophia, whether Justinian or his architect in reality intended the exterior to be finished at some future time, just as the façades of the Italian churches were often left to be finished by future generations; whether the original founder adopted the idea of getting a grand interior for the performance of the ritual at once, leaving the less important construction of the exterior out of consideration for the time? It would have been more possible to gain some idea about this from the actual study of the exterior before it was restored under the direction of Fossati in 1847 and the following year. He so far altered and renewed the exterior surfaces of a considerable part of the building that it can no longer furnish much evidence in the matter; and perhaps it never could have furnished this. But it seems to us very improbable that any man who had shown such ambition to produce a gorgeous interior should have been entirely indifferent about the exterior effect, and we lean to the impression that the exterior was never regarded as complete.

It is a common misapprehension to regard the church as dedicated to some special "Saint Sophia" of the calendar, a view which our usual way of translating the dedicatory title of the church serves to foster. But, literally, the church is dedicated not to any individual "saint" in the ordinary sense, but to "Sacred Wisdom," as opposed to the profane wisdom of which the goddess Minerva was the type. The recollection of this is not insignificant when we regard the general architectural style of the church; its large open area, its abundant light, seem quite opposed to the mysticism and gloom which subsequently gave the keynote to the aspect of the buildings of Mediæval Christianity; and such an effect is in accordance with the wider and grander idea suggested by the dedication. In regard to the form of plan adopted, we want the links which would enable us to connect it with its originating forms. The real history of the plan and section of St. Sophia is con-

nected, there can hardly be a doubt, with the Etruscan forms of architecture which so largely influenced the Romans, and the results of which, as far as that people were concerned, culminated in the Pantheon. It is probable that a good many Eastern churches between this and St. Sophia perished by fire, owing to the extensive use of wood made in their construction. We have St. George at Thessalonica as an early specimen, in which the plan of the building, with the circular form showing itself on the exterior, and the section of the dome, bear a very considerable resemblance to the Pantheon, with the difference, however, that the dome form is not shown externally, but is covered by a wooden roof, the outer walls being carried considerably above the springing of the dome. Mr. Fergusson classifies this as "Eastern Romanesque," a title which comprehensively expresses the historic relation of such a building. He assumes that it was erected by Christians, at about the approximate date of A.D. 400. The next known specimen after this, the church of SS. Sergius and Bacchus at Constantinople, brings us to Justinian himself, and may be regarded as a kind of trial on a small scale of the architectural scheme of St. Sophia; not that it was so intentionally, but under the circumstances, after the burning of Constantine's original St. Sophia, it might very well have been so regarded. Like the Pantheon, it exhibits the dome externally, and shows the tendency to the flatter section of dome which was afterwards adopted in the great church; and in plan it exhibits the principal characteristics of St. Sophia in a simple form; the square surrounding the dome, and the galleries and two-storied narthex. The main difference in St. Sophia is the lengthening out of the central space from a square to an oblong by the bold and happy introduction of the semi-domes from which the great dome springs, and which gives to the interior a unity of constructive effect such as hardly any other domed church possesses. In fact, the practical elements of architecture are as remarkably displayed in the interior as its æsthetic elements, and it is noticeable that, the rebuilding of the church having been rendered necessary in the first instance by the burning of the previous basilica, it was made a *sine qua non* by Justinian that it should be built exclusively of non-combustible materials, so that St. Sophia takes rank as the first fire-proof structure we know of that was intentionally so built. All the records of the construction of the building are indeed creditable not only to the ambition but to the practical good sense of the man who called it into existence, and boasted (probably quite within the mark) that he had surpassed Solomon.

In speaking of the historic position of the building in architecture, we may observe that recently a writer in *L'Art*, M. Léon Hugonnet, has started a somewhat fanciful theory in regard to the supposed influence of Egyptian upon Byzantine architecture. The architecture of Justinian, he says, seems to him to be *l'architecture Egyptienne rentrée dans l'architecture grecque"*; and he traces this assumed fact to the influences of the solitary saints of the Thebaïd, whose opinions governed the Christian world, and who introduced or recommended the introduction into Christian architecture of the forms they were familiar with in Egypt. It does not appear to us that this theory has more claim to serious consideration than a good many others which have been developed by French theorists on architecture, who have a great tendency to construct architectural relationships and theories of this kind out of their inner consciousness. That there is a connexion to be traced all the way back from the Gothic column to the Egyptian is true enough, but certainly the immediate connexion of Byzantine detail is with Greece and Rome, and the immediate connexion of its general scheme of building is with Rome. The only partial countenance that may seem to be given by St. Sophia to this Egyptian theory is in the battering of the lines of the masses of the external walls and counterforts; but considering how nervously anxious Justinian and his architects obviously were in regard to the stability of the building, from the way they piled mountains of buttresses against it, the idea of buttressing might have been sufficient to lead to this adoption of sloping lines, without any hints from Egypt or from the hermit saints, who we should imagine were about the last people to give much attention to architecture: and at all events, this portion of the building is architecturally the least important of all. Any critic who can trace direct Egyptian influence in the interior must, we should imagine, be very strongly biassed by a preconceived theory.

We have observed that the detail of St. Sophia was dependent on Greece as well as Rome, and it is curious that in the treatment of the carved capitals there is in many cases a much closer approximation to Greek feeling and forms than to Roman, and at the same time that the method of using, reproducing, and modifying these forms is, as we shall have occasion to observe, exceedingly capricious, even in contiguous parts of the same building. Some of the preliminary forms of capital a century earlier than St. Sophia are to be found in the basilican church of St. John at Constantinople, where there are capitals with a distinctly Roman or Classic outline, but with foliage assuming a tendency towards what were afterwards known as Byzantine forms. In some of the St. Sophia capitals, on the other hand, there seems to be a mingling of the old and new element in an opposite manner: the general forms of some of the capitals are Byzantine; for instance, they are longer in proportion, straighter lined, and less elegant than the Greek and Roman types of Corinthian capital on which they are founded, but the foliage bears a stronger resemblance to the Greek acanthus than to the Roman, and in some cases may fairly be said to be superior to either in its treatment, and the combination it exhibits of flowing line with sharp and crisp character and outline.

The transition of the building from being a Christian church to becoming a Mahommedan mosque took place in 1453, under the sultanship of Mohammed II., who built the first of the four minarets of curiously mongrel style, which now mark the four angles of the building externally, the one at the south east angle. Rather more than a century later Selim II. built the north-east minaret, and his successor, Amurath III., built the two at the western angles, adding also a great deal to the external buttressing, with well-meant but clumsy solicitude for the security of the structure. The building, however, towards modern times, was gradually sinking into a somewhat dilapidated and precarious state, and in 1847 the then sultan called in the architect Fossati to superintend a thorough repair of the building. Fossati, fortunately for himself, lived before the existence of a society for the protection of ancient buildings, under whose *régime* the Church of Sacred Wisdom would probably, by this time, be level with the ground. As far as regards the interior he seems to have used good judgment; there may be some question as to his treatment of the exterior. He found the church with many sinkings in the large dome arising from settlements in the substructure or in the buttresses, and not a few of the interior columns dangerously out of the perpendicular from the same cause,—in one or two cases columns which bear integral parts of the structure. All these were brought back to the vertical position except one, the handling of which was interfered with by the proximity and pressure of one of the minarets and its base and buttress. Portions of the large buttresses were rebuilt or re-cased, but the flying buttresses from them to the lowest ring of the great dome, which cut very awkwardly into the lines of the dome, were removed, and an iron chain put round the base of the dome instead. The lead over all the cupolas and other roofs was repaired or renewed. The surfaces of the great buttresses were finished up with a kind of imitation of coursed rusticated work in cement, and they were given also a new finish at the apex, a kind of semicircular saddleback with a circular ornament inserted in the front of the buttress, concentric with the lines of the capping. Fossati has preserved the original appearance of the exterior before he touched it in what purports to be an accurate view; and it must be admitted that in the building as it was previously there was a distinctly Oriental appearance which harmonised with its history and surroundings, and that the hand of the Western architect is somewhat too manifest in the external appearance as Fossati has left it. In the interior the ancient splendour was altogether dimmed. The inlays were dull with time, and the mosaics had been covered over with layers of plaster and other coverings to hide from the eyes of the faithful the idolatrous figures which they contained. This fact is perhaps a tribute to the permanent character of mosaic work, for it may be presumed that the Mussulman enthusiasts would have destroyed the mosaics altogether if they could easily have done so. Fossati, discovering accidentally the presence of some mosaic figures under the plaster in the vault of the north-west angle of the aisle, had other portions of the vaults uncovered, and it was then seen that the whole had been sumptuously decorated with gold mosaic, the gilding and ornaments on which were now renewed, while the obnoxious figures were ingeniously obliterated by powdering which could at any time be easily removed should the building pass into other hands, or should the followers of the Prophet relax their rule in regard to figures. In the same way there were found on the wall of the outer porch, over the door leading into the narthex, portraits in mosaic of Constantine and Justinian, and these have been covered again with a lightly-painted ornament in quasi-Arabic style, which at once conceals and protects them. The building thus came out in something like its old splendour so far as colour effect was concerned; and the furniture was renewed in a sumptuous manner. The effect of this cannot be well realised in an engraving; the gilt chandeliers, for instance, stand out in reality with great brightness in the total effect, while neither that nor the effect of the mosaic can be conveyed in black and white; but the illustration* gives correctly the grouping and effect of the architectural details (of which a word more just now) and of the principal objects in the building, which, indeed, are not many; the simplicity of Mahommedan worship having its advantage from an architectural point of view in this way at least, that it leaves opportunity for a large extent of open and unencumbered floor space, nothing being needed for the majority of the worshippers beyond a spread of carpets over the floor to kneel on. The octagonal erection on the left of the view is what in English would be called the Sultan's pew, which is also a sumptuous erection covered with gilding, and surrounded to the greater part of its height by rich tracery, which avails to hide the royal worshipper from the view of the people, though leaving him with a full view of everything. It need hardly be observed that this is a modern addition. Two remarks may be made, before quitting this part of the subject, in regard to the effect exercised by Mahommedan arrangements and furniture on the interior of the building. One of these arises from the fact that the building, not having been built as a mosque, does not front towards Mecca. The Mahommedan conquerors could not alter the orientation of the building; but as your true Mussulman always prays kneeling or standing on a mat or carpet, it occurred to them to right the matter by arranging the carpets in reference to Mecca, and at right angles with the true Mahommedan orientation, so as to run in oblique lines across the floor. This method being religiously carried out in every part of the building, and arresting the eye at once, gives an idea of the whole structure having been built askew; but, though a rather provoking effect architecturally, the incident is so interesting in its associations and suggestions that perhaps no one would wish it otherwise. The other point is a very different incident, too prominent in every view of the interior, namely, the hideous effect of the great circular panels, with texts from the Koran inscribed upon them in colossal characters, which are painfully conspicuous in our view of the interior. They cut up the architecture most cruelly, and greatly injure the scale of the building; and it is a marked instance of the essentially Puritan character (except in one particular) of the Mahommedan faith, that it exhibits so strongly in this case that absolute indifference to artistic effect as compared with spiritual and moral enlightenment, which is one of the leading characteristics of all Puritanism.

Running over, in conclusion, some of the points in the architectural scheme of the building, we are struck with the curious mingling of Classic with Christian associations in the architecture of this once Christian temple. We enter the narthex, at the south end, through a porch with an almost purely Classical cornice, Roman in style, and through a door of bronze in an almost pure Greek style, evidently brought from some Pagan shrine. The shafts of the columns in one corner come, so tradition has it, from some disused temple at Ephesus; in another we find reputed spoils from Baalbec, in some cases various-sized drums of shafts joined by metal rings. In the arcades on the upper story over the central part of the nave, we have the front row of columns, those which form the screen

* See p. 452.

visible from the body of the church, with quasi-Corinthian capitals, retaining very much the general outline and character of the Corinthian capital, only with smaller volutes and somewhat different type of foliage. Immediately behind these, the columns which carry the springers of the vaulting have a compound capital, consisting of the straight-lined carved block peculiar to Byzantine architecture mounted on an almost pure Roman Ionic capital. Everywhere there is this curious transformation of old forms, or mingling of old details with new combinations, proclaiming that architecture was at this time entering, or preparing to enter, on a new path.

Going back for a moment to the door between the entrance-porch and the narthex, mentioned before, we find in the simple yet rich architecture of the narthex another application of Classic forms. Here the supports are massive square pilasters, with a capital in three stages, which somewhat suggests the idea of a portion of a Classic architrave, with its crown moulding and its two facets, only all elaborately carved. This is, at least, far better than the Roman idea of twisting the whole members of an entablature round the top of a column. The roof is a simple quadripartite vault; a domical roofing would have been more completely in keeping with the character of the main portion of the building. The treatment of the angles of the plan, with their screen of columns arranged in a quadrant separating them from the main area, is most happy, both above and below; it includes something of the real poetry of architecture, giving at each turn a new view of the structure,—a new perspective effect. This would strike even the unlearned spectator, but the architect derives still greater pleasure from the beautiful and architecturally truthful treatment of the great piers and the interspaces between them; the piers are almost unbroken solid masses, only diversified by inlay; the arcades between filling up what is constructionally a void in the most appropriate and graceful manner, giving breadth and unity to the whole while clearly defining the supports of the building. The advantage in the way of internal effect, from the low pitch of the dome, which enables the eye to take in at once and appreciate its real size, has been often remarked on and contrasted with the less satisfactory internal effect of the loftier dome of the great Latin cathedral; but not so often has the peculiarly beautiful lighting of the dome been commented on, the manner in which light has been poured in through what is the heaviest part of the section of the dome, yet without obliterating the appearance of constructive security. The whole idea of the treatment and roofing of the great central compartment is one of the most noble architectural conceptions that has ever been carried out, and the interior is not less remarkable for its grandeur as a whole than for its picturesqueness in detail, and the interest and beauty of its decoration.

ARTISTIC PROSPECTS OF THE MODERN RENAISSANCE.

Beneath the briefest introspective glance of a generation too feverishly emulous of advance to linger upon any subject whatever, the fact of a present certain human moil must become sufficiently luminous: a moil that, being material, moral, intellectual, and imaginative, can be covered by the most comprehensive epithet alone.

Not that the age has gone mad; far from it: yet does it evince a want of rest and coherence that should, speculatively, affect its departmental functions. Art, in her various phases, must peculiarly suffer; for while Science goes with judicial imperturbability straight for his mark, accepting rebuffs with fortitude, wishing to see nothing but the sparkling grain of truth at the bottom of his crucible; she is the enchantress who loves to spread her gorgeous skeins of fancy around her, developing at leisure the woof that is to take captive the minds of men with the novelty of a creation. The renaissance in progress is, indeed, as distinguished from the earlier period of literary and artistic revival, expansive rather than consecutive, affecting the entire body social. Thus, political problems are enlarging their spheres of activity, while science and dogmatic theology, like armed powers keeping to the neutral zone and equally prepared to fight as fraternise, seem awaiting an umpire.

Such, however, is the marvellous fruitage of inductive science, that the field of inquiry is kept crowded with ill-assorted wonders, and a spirit of tentative compromise which aims at patching current theories rather than launching new ones, is the rule.

Our forefathers, whether of the past century or the past cycle, might project their minds into the most grotesque regions of thought without being challenged. We cannot afford that. The front files of the on-coming future tread so closely upon the heels of the present that the dread of exposure is greater than our greed for notoriety, and, ceasing to theorise, we too often cease to classify. Speaking the truth was what our forefathers had chiefly to fear. Not so we. We need not, indeed, recant a sincere conviction, adding the stealthy reservation *e pur muove*. Ours is an epoch when heroes might flourish; but the fear of ridicule, more potent than the rack, keeps in the bounds of decorum, if not of mediocrity, us of whom Science, the athlete, has a lead of many lengths.

Using the term "Renaissance" in the limited sense we are accustomed to attach to it, we can, without absolutely forgetting the flood of social turbulence which is bearing us along with it, contrast current aspects of thought with those obtaining at the earlier historical period. The Renaissance of history was a new birth of art and of letters, yet by no means so abruptly defined as we are apt to imagine. Latent in cloister and cell, the embers of a new culture smouldered long before they burst into flame. A Venerable Bede, a Chaucer, not inadequately represented two of the Muses. Ireland was but declining from her brief zenith of native civilisation. But, until the invention of printing, learning could not become popular, for pontifical Catholicity failed to do what the ancient States, with their profound reverence for Nature, did. Christianity had triumphed, but over much that was excellent as well as over much that was hateful. The Roman had his pride of citizenship and his possible apotheosis; the Athenian, his sympathetic union with Nature's mysterious legion of gods and forces; but the Christian layman of what we term the Dark Ages was not encouraged to assert the superiority of the human soul within him, being kept within conservative channels of inquiry by the clerics, lest worse might befal him. When, however, Faust and Guttenberg, together with others, had completed their modest plan for the diffusion of learning, Mind unfolded into a beauteous flower, which was the logical sequence of the bud that the Church had so long pruned and tended.

Faith was to the intellect of the Renaissance what the worship of nature and of power was to the ancients,—the nucleus around which gathered all the accretions of learning.

Art quickly ran through its invariable course of development: architecture, poetry, painting, and music. The former had reached much excellence, as our old abbeys remain to show; yet the genius of no Michelangelo had been enlisted, either in the grander walks of architecture, or in the embellishment of cathedrals with frescoes and with carving. If it be in the nature of things that architecture takes precedence of the other arts in point of time, it is equally true that she embodies the leading principle of the day. The vastness of Assyrian and Egyptian designs, the chasteness of the Grecian Orders, the dignity of the Roman works, the ornate effeminacy of the Aztec temples, are distinctive of race and sentiment. The Roman arch, too, if a comparatively late idea, need not be mistaken for the Saxon one which resembles it, still less for the Norman. Mediæval church architecture, largely as its prevalent form, the Gothic, has borrowed from Saracenic models, is characteristic and strongly typed, a fact that it needs no skilled architect to discover. Viewing one of those old buildings, one feels that each part has its meaning, and that an ardent central idea has taken to itself flesh of stone and mortar. It is not thus with the architecture of our times. It is not that our modern Renaissance lacks vigour; but that no vivid idea lies at its centre; still more, that bases of research are shifting from day to day, and human opinion shifting with them: the light that we have is dazzling, but comes through no one channel; diffusive and evanescent, it offers no background of shadow for purposes of contrast. Perhaps, if one half the kingdom were depopulated and conserved for Patagonian savages, while our bishops made their *autos da fé* of our literature and of our scientists in the squares, we might, between awe for Mother Church and the perverse human instinct to prove its superiority over its neighbours, develop both a faith and a genius. It must not be overlooked, however, that the spirit of liberty, which was a suckling once, is a giant now, and rebellion against the paternal hand which used to keep thought in its channels, might destroy the parallel. Though art may be the loser, we prefer to make, each, his points and his failures on his separate account.

Progress is the motto of our age, but so rapid is its march that, throwing away its *impedimenta* as irksome, it is now and then astounded to find that it recognises neither itself nor its surroundings. The old distinction of gases, liquids and solids is known to be fallacious, while certain gases are coming to be considered as metals.

The so-called imponderables, again, have undergone a vast change in estimation. Our regard for law leads us to shun the theory of the existence of matter exempt from the property of gravity, while the "correlation of forces" puts a fresh aspect upon molecular possibilities. This correlation is becoming intensified into a true "conversion" of forces, and the alchemist's dream of the transmutation of metals is moving into line with other possibilities once more. Chemical nomenclature is so altered that Dalton, Cavendish, even Faraday, the latest of the great fraternity, would, if living, have to discard much, and re-arrange more. Subject to incessant eliminations, the intellectual field that comes under review of any one life is necessarily vague, circumscribed, and out of apparent consecutive dependence upon preceding lines of investigation. The scientist himself may reject errors intelligently, and carry human knowledge to a higher stage, but, to numbers, this want of fixity gives irresolution, and to none more than to followers of the arts, whose knowledge is less critical than their sympathies are expansive.

Want of certainty of touch either causes timidity in conception and weakness in execution, or inflates with the prurient immodesty of shallow thought simulating genius. In architecture, gaudy effect usurps well-balanced design. Scientific aids of drainage, lighting, and heating are, though loudly professed, poorly invoked. When anything more than a pretence, they are seldom decently subordinated to the plan. Invention lags, so that posterity will not be able to point with confidence to representative specimens of Victorian architecture: adaptation is our servile climax.

No doubt we are better housed, clad, and fed, than our forefathers, and that is much. We also are popularising knowledge with a view to awakening a national interest for art. Nor can it be concealed that we are struggling to regain, in very many departments, the forgotten secrets of ancient excellence. With our art schools, and other propaganda of the day, we may hope to develop public taste up to the level of its capacities, and these means have been unexpectedly fertile already in refining or educing the lower functions of taste. Our more solid triumphs may be to come, but are they likely to be as glorious as those of the Renaissance of history? This interesting question can only be conjecturally answered, but the chances are that the Renaissance which has begun in our day will not, itself, develop a high order of genius in any artistic department, but that its reaction will. Our age is scattering more seed, than it is garnering in the harvest. Scientific research has been busily promulgating facts which our successors must arrange.

Law is hinted as likely to underlie this or that, but no clear consensus of laws has been discovered, while the mind of this century, fevered and worn, is ill-adapted to condense from the chaotic sum of facts before it a vivid and coherent cosmogony replete with human feeling, such as is demanded of high art. The social state reacts upon the individual: a man is a unit now, a cog in a great machine; labour is departmental and perfunctory. As regards literature, it is not food for thought that people seek, but devices for obviating thought's necessity. Fictional writing is, in the main, flimsy and meretricious,—emotional phases of character being preferred to the deeper discoveries of the great masters. Even this tendency towards character-portrayal is, since George Eliot's death, left without a high exemplar. The poetry of the period is maudlin and insincere; the drama, composed either of adaptations of French plays, or of sensational figments too powerfully concentrated to have literary value, and touching none of the nobler qualities inherent to human nature. If there be a characteristic that more than any other belongs to modern imagina-

tive thought, it is a vague vastness relieved only by its complement: petty frivolity. The former tone has its advantages, the latter, none. The first may be the *nimbus*, containing the germ of a new mental and moral birth,—climax of the Renaissance in progress; the other is a common mark of unsettled purpose.

We are selfish, living more for ourselves and less for posterity than our predecessors. Reverting for a moment to architecture, it is true the Thames Embankment and kindred works will stand, evidences of engineering skill, yet with no pretensions to character beyond those of vastness and utility; but the railways, the telegraph lines, the gas and water systems, our great city itself, are for the living; our legacy is one of ideas alone.

We have built no universities in our day, but we have the gigantic School Board system; no cathedrals, but tabernacles and rotundas to spare, all of which will come down and, possibly, be renewed, while Westminster Abbey waxes hoarier and more firmly knit.

Where the grand vagueness which is the characteristic of our public architecture under its best manifestation has no scope, the frivolity of the contained idea is often painfully evident.

In the domain of verse, Tennyson is massive, but unsymmetrical; quaint, yet devoid of humour. Browning, for inharmonious energy, is unique. Swinburne, melodious as are his numbers, lives in a world apart from ours. Had circumstances favoured, he must have been a representative poet, but he turns from it in despair, to hold commune with Eros in Arcadian groves.

If we turn to painting, we see a spurious sentimentality usurping the place of legitimate human feeling. The desire to achieve sublimity is there, but the power is wanting. Realism is aspired to, but honest work of flesh and form is slurred. As is the case when Art lacks force, weak allegory is used to cover defects. "Suggestiveness" is, also, an artistic excellence much aimed at, a favourite subject being the juvenile figure and a member of the brute creation. Let it be a child and a dog. Contrast is, here, between beings of diverse species, Nature's distinction, not the artist's.

Music, the capital of the graceful column of the arts, partakes of the vagaries of the modern "æstheticism" which is common to those already touched upon. That which has been termed the "music of the future," as especially implying the Wagnerian school, is really the music of to-day. Vague, mystic, inchoate, it grasps at the ideal it cannot seize, scorning the limits within which the great masters of melody found it necessary to confine their genius. As for our popular melodies, they are remarkable in not possessing melody at all: lacking a core, our tumultuous renaissance runs its sentiment to waste. We cannot turn backward the wheels of progress, and may not, amidst the distractions of a nervously hurried material existence, look for a revival of that glow of heroic enthusiasm with which Mediæval thought, then young, and fresh, and simple, slipped the leash in which it had been confined, but where it had gained strength and sincerity. Our hope is that the reaction from all the oppressive materialism and uncandid sentiment that clog the art of to-day may intensify; that humanity may, by scientist, artist, and poet, whether of word or of tone, be reinstated as lord over the blind forces of nature, instead of being widely regarded as but an inferior force, without the dignity that belongs to human personality.

The Church preached the close union between divine and human; we may hold up man's sublimity as remodeller of the Natural Arcanum, when, no longer a football at the mercy of the Fates, as was the ancient conception, nor the vehicle of miracle, as was the theory of the monks, man may be seen to move freely and intelligently among the elements, as deputed lord.

The apotheosis of our great men of science need not follow, for our temple should be bathed in the white, cold light that kills credulity. We lack the spark of self-respect which underlies all excellence; humanity must feel itself ennobled, and the arts, seizing upon the idea, will weave around it with mathematical accuracy the web of contemporary thought and revised scientific teaching. The renaissance will, under such a reaction, prove one of classical purity as well as of unexampled vigour.

The Savoy Theatre.—The opening of this theatre, described by us a fortnight ago, is postponed until Monday evening next, in order to perfect the electric-lighting arrangements.

HAMPTON COURT AND VERSAILLES.

As in so many other cases, it is perhaps owing to its literary celebrity,—a celebrity that is made for it by French writers,—that Versailles is so much more famous than Hampton Court. What Englishman, what stranger, considers his visit to Paris complete without having passed at least a day at Versailles,—if he may not see the fountains play, at least to wander through the interminable apartments of the huge palace?—but how many visitors are there to London who leave our shores without having considered it necessary to spend a day,—an afternoon, indeed, is sufficient,—at Hampton Court Palace? And yet, looked at impartially, Hampton Court is more interesting, or should be so, than Versailles. If comparison were necessary from their historical and artistic interest, it would be much more the deserted palace of Fontainebleau than Versailles that Hampton Court might be said to resemble, though old John Evelyn remarked, now more than 200 years ago, that Fontainebleau "was nothing so stately and uniform as Hampton Court" (March 7, 1644). At the time that Evelyn visited Fontainebleau, the site of the yet unbuilt palace of Versailles was a sandy, unhealthy plain. Fontainebleau lies some twenty-four miles or so from Paris, while Versailles and Hampton Court stand nearer to their capitals, the former ten miles from Paris, the latter fifteen miles from London.

Though it cannot be said of Hampton Court, as it can of Versailles, that from the moment of its completion it has been a royal residence, the annals of Hampton Court are closely connected with the lives of more than one of our kings and queens; but its modest proportions, while long affording ample accommodation to our English ideas of regal splendour, cannot certainly be said to vie with those of the recklessly-erected acres of Louis XIV.'s hobby. Happily, for the memory of our rulers, no blot exists in the story of the creation of Hampton Court such as stains the early annals of Versailles. When Wolsey determined to build the palace he was so soon to give to his royal master, he expressly sought the most healthy spot to be found near London, and he fixed on Hampton Court; but no such precautions did Louis XIV. use when, a century later, he determined on Versailles as the site of his future residence.

The story of the Aladdin palace which Louis XIV. called up from the unhealthy desert of Versailles is familiar to every reader of French history, and at what cruel expense of life the hobby was at length carried out, contemporary writers bear sufficient evidence. Thousands of workmen and soldiers were employed to bring water to the sandy plain, and the "Letters of Mdme. de Sévigné" and the "Memoirs of Mdme. de Lafayette" tell us of the terrible effect produced by the miasma exhaled by the freshly-disturbed earth; every night, carts filled with the dead defiled silently along the road. One of the most eloquent of the chapters in the "Memoirs of Saint-Simon" is devoted to an attack on the creation of Versailles. Delightful St. Germains, long the pleasant home of the court (Louis XIV. was born at St. Germains, where, in later years, he was to lodge our English "Pretender"), he had determined to leave; tradition says, because the distant view of the cathedral of St. Denis, the burial-place of the French kings, disturbed his "immortal" grandeur. If Skelton, in some measure the Saint-Simon of Henry VIII.'s reign, has satirised in his biting lines the erection by Wolsey of so regal a residence as Hampton Court, his accusations are but the witty expression of the envy which Stow tells us was excited at court by the cardinal's magnificence. There is nothing analogous to the simple narration by contemporaries of the facts connected with "that cruel folly, that Versailles of Louis XIV.,—that master-piece, so ruinous and in such bad taste,—where whole changes of forests and water have buried so much gold."

What Versailles cost will probably never be known; it has even been said that Louis XIV., frightened at the terrible cost, burnt all the registers. As far back as 1801, however, a distinguished architect, M. Guillaumot, in the course of some observations on the injurious effect of the ignorant objections raised by the unprofessional public against the enormous expense of the building of public monuments, brought forward some interesting results of a lengthy research among the State documents; among these he finally discovered some accounts relative to the erection of Versailles. The tables prepared by M. Guillaumot comprise the expenses from 1674 to 1690, and we give these figures as affording a curious comparison with some figures given recently in these columns relating to the expenses of the great hall of Hampton Court Palace.

Masonry, &c., of Versailles and its dependencies, 42½ millions of *livres* (francs); timber work, 5 millions; slating, 1½ million; lead work, 9 millions; carpentry, 5½ millions; locks, 4½ millions; glass, half a million; mirrors, half a million; paintings, gildings,—not pictures,—3½ millions; sculptures, not antiques, 5½ millions; marble-work, 10 millions; bronzes, 4 millions; iron and lead pipes, including those for the famous "machine de Marly," 4½ millions; tiles, paving-stones, and cement, 2½ millions; gardening, fountains, and rockeries, 4½ millions; excavating and removal of earth, 12 millions; divers extraordinary expenses, 6 millions; the Château de Clagny, 4 millions; the "Machine de Marly," exclusive of the Versailles expenses (this machine brought, as it still brings, water from the Seine to the fountains of Versailles), 7½ millions; the aqueduct of Maintenon, 17½ millions; the Château de Marly, 9 millions; indemnities to landowners, 12 millions; purchase of old pictures and antique statues, 1 million; gold and silver stuffs, 2 millions; plate, 6½ millions; crystals, agates, &c., 1 million; architect's fees, 2 millions; expenses previously to 1664, 3 millions; a total of something like 190 millions of francs, though 400 millions of francs is thought much nearer the sum expended than the lesser figure; a very large number of items being omitted in the above account.

Hampton Court cannot tell such a tale of pompous expenditure, and if its simple yet effective architecture, its prim, well-laid-out and well-kept gardens, cannot be said to bear comparison with the splendours of Le Nôtre's botanical skill and Mansart's royal designs, happily the story of its various occupants can equally, with difficulty, be compared with that of Versailles in its connexion with the French monarchy during its most dissolute days. But putting aside the past both of Hampton Court and Versailles, a comparison between the present condition of the quiet, suggestive, old English palace on the banks of the Thames, and the upstart, overwhelming, grandeur of Versailles, there can be scarcely differing views that with the former rests the superiority. Mr. James, the American writer, tells us in his most recent tale that the Americans are especially fond of Versailles, because there they expect to find uninjured the thorough life of the "old *régime*," and he expresses amusingly the disappointment of one of his characters who on visiting Versailles, with a view to obtaining a knowledge of the mode of life, finds the old town all but occupied by his republican countrymen. We strongly suspect that our impressionable cousins would not meet with such a disappointment were they led to expect to find at Hampton Court the relics of our old monarchy.

Versailles, with its miles upon miles of parquetried floors, its "gilded saloons," acres of meaningless decorations (Lebrun, &c.), tells only too plainly its history, over which it will be found that a false glamour has been successfully thrown. From an artistic point of view there cannot, in the mind of the thoughtful visitor, be two opinions as to the superiority of Hampton Court over Versailles; indeed, this was the point at which we had desired to arrive more immediately than we have done. The comparison which may be drawn between the existing collections of art, gathered respectively at Hampton Court and at Versailles, cannot be said to lie in favour of the latter.

There has recently been published an excellent catalogue of the pictures collected at Hampton Court. It lies in the power of any reader to compare Mr. Law's interesting volume,—or, indeed, for ordinary purposes the little guides that exist for Hampton Court will be found amply sufficient,—with any catalogue or notice of the artistic contents of Versailles; the comparison thus easily afforded will, we think, be found enough to justify our opinion. It is not alone from the fact that the creation of Wolsey's Palace takes us back nearer than Versailles to what the Italians well understand by "the epoch,"—the great epoch of artistic history,—that the contents of Hampton Court will be found to possess an interest to the art-student that is wanting at Versailles. Putting aside the now removed Raffaelle cartoons,—once the glory of Hampton Court,—as also the Mantegna tempera

pictures, there will be found abundance of other material for much interesting and profitable inquiry. The portrait collection of Versailles,—almost without exception modern,—will scarcely compare with the collection of portraits at Hampton Court: the Lely beauties, so long preserved at Windsor, and known, indeed, in the history of English art under the name which Walpole gives them of "the Windsor Beauties"; the Knellers, the Van Somers, the Honthorsts, the several superb Italian portraits,—among them a masterpiece by Titian,—the characteristic Velasquez, the Van Dycks, the Holbeins. Where at Versailles can be shown portraits as interesting as that of Lord Surrey, the Zucchero representing Queen Elizabeth in a charming fancy dress, several Gainsboroughs, and a dozen more other rarities of the painter's and portraitist's art? Horace Vernet's acres of much-vaunted battle-pieces we can look on, in the present day of Alfred de Neuville and Miss Thompson's triumphs, with much less enthusiasm than the generation of Louis Philippe's vigorously attudinising generals and over-costumed statesmen.

This is the season of the year when many English people are already abroad, or are going abroad; to those who have not as yet crossed the Channel and have a little time to spend in London before going to Paris, we would say, Do not fail before leaving England to pass an afternoon at least at Hampton Court in its quiet seclusion, undisturbed by the rush of the excited tourists that for ever seem to delight in rousing the hollow echoes of the long galleries of Versailles, and making tingle against each other the thousand rainbow-coloured drops of the glittering chandeliers in the famed *galerie des glaces*.

It is not a little strange that the settlement immediately in the neighbourhood of the English palace possesses so little charm compared with the surroundings of Versailles. Versailles leaves an impression on the minds of most strangers of being a delightful place of residence, and many Parisians of fame have indeed found it so; probably it is to this fact that Versailles owes so much of its charm. Such a feature is all the more remarkable as the natural position of Hampton Court on the pleasant banks of the Thames is one that is far superior to that of Versailles, surrounded by its miles of uninteresting flat plain.

THE PRESENT CONDITION AND HOPES OF ARCHITECTURE.

If the English lover of the Græco-Roman and Italian columnar style feels surprised at the existence of dissatisfaction with this architecture evinced by the oft-repeated complaint of our want of a national style, he must feel infinitely more so on discovering that a similar dissatisfaction with the style exists among the Italians themselves; which is the fact, if the declared persuasion of an eminent critic (Signor Camilla Boito) of the necessity for a new style, and attempt to invent one, together with his being allowed opportunity of embodying the result in important buildings, are to be taken as an indication of the public feeling.

Let us consider what the columnar architecture is, which has come down to us through many hands, and the foreshadowing of which formed the material grandeur of the early and renowned capitals of the world,—Nineveh, Babylon, Persepolis,—which was the glory of Athens, the magnificence of Rome; and for the embodied relics of which at the revival of art the greatest architects of Italy dug as for hidden treasures. The classical columnar ordinance of the Greeks and Romans I look upon as the essential nucleus or framework of the architecture of the world, for which we can imagine no substitute, and which must have appeared had the temple solemnities of Egyptians and Greeks never required it. It lay, a divine creation, like geometry or analysis, in the womb of chaos, and must of necessity have been called forth by the first imaginative and cultured people. It is, like the mathematics, rather a discovery than an invention of man. It is not occasional and peculiar, but symbolical and universal. Whatever new building material was introduced into architecture, or whatever material becomes dominant, the colonnade will not become obsolete. The simple and natural beauty of insulated columns, the magic of peristylar perspective, must ever charm the imagination of the educated and uneducated, the young and the old. The exclusive admirer of the Gothic should remember that that style is a lineal descendant of the Classic, and owes to the Classic its most pleasing features. The most beautiful Gothic cathedrals are those that show most reminiscence of the colonnade or round columns, a dearth of which always produces a harsh, liney appearance.

The same may be said of the Byzantine, Saracenic, and other styles. In fact, in the Greek temple of Corinth were lodged the germs or principles of the whole architecture of the world, as are the rudiments of the future plant in the seed. For this reason it is that in treating of the position and hopes of architecture I confine myself chiefly to classical, and not from any narrowness of view and aim, or lack of sympathy with the other beautiful and interesting, and equally true phase of it.

You meet with the colonnade, or anticipations or reminiscences of it, every where,—in the Hindoo and Buddhist temples, and cave temples, and in palaces, tombs, and mosques of all Mahommedan lands. Architectural ambition has almost always embodied itself and broken forth in columnar grandeur; as if the beauty and capacity for sublimity of groves of columns had smitten the imagination of every people possessed of one on the earth.

It is absurd to go into raptures over the Parthenon and be, at the same time, indifferent or opposed to the columnar style, because all that charms us in that building belongs to the columnar style, every example of which is susceptible more or less of the beauty and harmony of the Parthenon, which, denuded of its sculpture, remains exquisite architecture, proving it, like female loveliness, independent of the foreign aid of ornament. But the quality of being self-dependent or having need of nothing bears most analogy to the excellence or perfection of the Supreme Being, and therefore most divine. It is an attribute of the style that eminently fits it for the solemn temple, which it will as truthfully form as the gorgeous palace. And if it cannot express so vividly the hopes and aspirations of the Christian as the Gothic, its abstinence from the attempt is to the preservation of beauty in its sacred embodiments, and renders them a truer reflection of that grace of external nature which is the veil of the Eternal Cause, and nearer to the fashion of the shrine which we may suppose He would himself have built to his worship; more likewise in unison with the holy and beautiful breathed from the Lyre of Inspiration.

Let no one suppose the columnar architecture a mere stereotyped formula of three or four columns; for the scope for variation on their capitals alone is infinite. To it belongs the dome in its utmost chasteness and grandeur.

This is the style which certain architects and critics would supersede by some new invention.

The sudden appearance and general introduction of a new style has no precedent in the history of architecture, even among the most artistic nations. We can trace every known style back to its origin and descent from one or more parent styles, generally to two, except the Pelasgic, Egyptian, and Assyrian, their origin being lost in the night of time, and no remains of earlier styles having been found. New styles, it is true, have been evolved spontaneously and slowly by the mingling of two others, and may be again,—the growth of similar circumstances; but no style was ever called out of chaos. To reject the columnar ordinance of the Greeks and Romans, and seek for new elements, is as absurd as to reject all that has been wrought out in philology and literature, and go back to Cadmus or to hieroglyphics. He who does so places himself in a worse position than the first nations. He is like a poet by nature, endowed with the highest gifts perhaps,

> "The vision and the faculty divine,
> Yet wanting the accomplishment of verse."

He forgets, or is ignorant, that architectural creation does not consist in calling architectural designs from nothing; that it matters not how much an architect is indebted to other men for his materials, if he combines those materials according to new affinities and "adorns nature with a new thing." Nor need he be surprised if any architectural style which is the child of his own brain, does not find favour, or that it results in something the embodiments of which in buildings it would be flattery to call architecture. He must, indeed, soon discover that his only chance of competing with the past in architecture is to avail himself of the labours of his predecessors, and adopt the columnar ordinance of the Greeks and Romans, or the arcuated system of the Mediævalists.

Than such movements and the criticism, English or Italian, that leads to them, nothing can be more mischievous; for the faith of the student in the truth and capability of the style, which it is calculated to unsettle, is essential to his progress; and architectural students are in vain exhorted to diligence and enthusiasm in the pursuit of their art when they are left in doubt by conflicting criticism what phase of it to pursue, or whether any phase of it is worthy of their acceptance. Faith is as essential in art as it is in religion; for "if the trumpet give an uncertain sound, who shall prepare himself to the battle?"

But for this criticism there would be little need of inciting to zeal in the fascinating study of architecture. As in religion, unshaken faith would be followed by love in the breast of the student for one or another of the styles of the day that solicit his attention, according to his natural or acquired predilection.

Though, on the other hand, there are not wanting critics who, from dissatisfaction with present practice, or late efforts at originality, counsel the mere adapting the old productions of this style to modern purposes, and even go so far as to suggest copying, I will not suppose that the descendants of the ancient Greeks and Romans,—men with more or less of the blood of Phidias and Praxiteles in their veins, for such are the modern Italians,—are ignorant of the right use of architectural examples to the architect, or unable to grasp the true principles of their combination. I cannot but suppose that Italy contains hosts of men with sufficient imagination,—the vital quality in all art and artists,—to fuse into other harmonious examples the same elements from which those elder buildings were composed; in other words, of making the same use of the elements so abundantly placed at their command that Sansovino and Palladio made; which does not need a succession of eminently gifted men. Men of ordinary abilities will suffice if they have any reasonable depth of artistic feeling, which gives a power and insight to the intellect it would not otherwise possess.

Ancient examples are to be neither copied nor adapted; both practices are unworthy of an architect. Those who recommend them forget, or are ignorant of the epochal, local, and ethnographic nature of architecture,—the relation it bears to its own age and country. Ancient buildings cannot be exemplars for all times and places. They are to be mentally dissolved and recombined into other forms,—decomposed and recomposed.

Nothing is more natural than for the Italians to adopt this columnar ordinance, for it is their own rightful property,—the bequest of their forefathers. Italian architecture is not strictly a revival or resurrection of the Græco-Roman architecture, as it is generally supposed to be, for that style never died at Rome, which, owing chiefly perhaps to the sacred character of the Pontiffs, preserved in a greater degree than any other city the traces of ancient civilisation. The night, it has been said, which descended upon her was the night of an Arctic summer. The dawn began to reappear ere the last reflection of the preceding sunset had faded from the horizon. A stream, narrow indeed, but pure, of that architecture came down embodied in the Christian basilicas at Rome, which are not Romanesque, but Roman, whence it issued into all the countries of Europe. Certainly it was not revived in the sense in which Greek literature or painting or sculpture was revived. Greek literature had been lost to Europe for centuries, and survived only among the Saracens and Eastern Romans, from whom it was first recovered in the thirteenth century. Greek painting had been lost till recovered by Cimabûé and Giotto from the Byzantine school; so had sculpture, of which Pisano was the modern restorer. But Græco-Roman architecture, alive from Classic times, was present in all its beauty at the capital of the world when it was wanted, and, blended with Italian Romanesque, contributed to the inspiration of the Venetian, Roman, Florentine, and other varieties of the Italian in the sixteenth century.

I can imagine nothing more natural or proper than the resumption of the ancient architecture by the Italians, nor than the general course which it took in Italy in the fifteenth and sixteenth centuries. Let us glance at its history. It is probable that Brunelleschi was the first to infuse a purely antique spirit into his works, among which may be cited the cupola of the cathedral of Florence, the erection of which opened the way to the greatest architectural

enterprises of modern Europe, the Church of the Holy Ghost, and the Pitti Palace in the same city. He was followed by L. B. Alberti, who emulated the achievements of his predecessor, and in some respects excelled them. The churches of St. Francesco at Rimini, and of St. Andrea at Mantua, with the Palace Rucellai at Florence, are among the best of his works. Michelozzo, a scholar of Brunelleschi's, and other Florentine architects, followed Alberti, and were seconded in developing and applying the style by Bramante, who had practised in the former one. The Belvedere Court of the Vatican, the Court of the Loggia, and the Sora Palace at Rome, are specimens of his graceful manner. Peruzzi showed greater freedom in the use of his materials, as witness the palaces Farnesina and Massimi at Rome, and was seconded by Antonio Sangallo and by Raffaelle, in whose hands and those of Michelangelo, Vignola, San Michele, Sansovino, Palladio, and others, the style of ancient Rome was restored in all its grace and grandeur, and so expanded by additional elements, in its application to new uses, as to be rendered a distinct style, and in some respects a more consistent one than its antique parent or prototype.

No trail of the serpent seems to have been descried on it by any one of the architects just named, and many of them were men of strong religious feeling. They probably remembered that it had been in the service of Christianity in the Basilicas before mentioned since the time of Constantine the Great, long enough to atone for its guilt, if it had incurred any, in the service of a false religion; if, indeed, they did not feel that there is a holiness in real architecture, as in all true art, which no alliance with heathenism or anything else could take away. Such was the course of architecture in Italy, and the career of its most eminent professors,—the greatest architects, painters, and sculptors of the most accomplished age of the world since that of Pericles.

Now, if the human heart and imagination is the immediate fountain of all poetry and art, it is exceedingly absurd to suppose that the artistic instincts of such men, including one I have not yet named, Leonardo da Vinci, who, being an architect, was also concerned in the movement, — a painter, sculptor, poet, the greatest intellect of the fifteenth century, and seemingly of universal and superhuman knowledge,—should have betrayed them into a wrong path,—a path in which originality and progress was impossible,—and that another galaxy of great artists should have blindly followed them. I conceive that such men would have gone right by the mere force of their imaginations, and have been more likely to make a stride in the right direction than to slide into a wrong one. I conceive that such men as Da Vinci, Michelangelo, and Raffaelle, whose names are almost synonymous with beauty and sublimity,—who had grasped the whole realm of design, and were almost the inventors of chiaroscuro in painting,—would leave examples of a proper union between the three arts, and advance the style in every respect as no mere architect could. We should remember that artists such as they, — of the highest order that ever appeared on earth, — have always uniform, well-balanced minds, with judgments commensurate with imagination. If it be argued that true architecture is that on which its authors have impressed the leading thought of the age, I answer, the revival of the productions of Classic antiquity was the great thought of that age.

But this style is greater than its examples; and its highest reach of monumental grandeur or utmost possibility is not to be judged by its most important embodiment,—I mean, of course, that most costly and ambitious structure ever reared to the honour of Christ,—St. Peter's Church at Rome,—which, from some cause or other, does justice neither to the capabilities of the style nor the genius of the great architects employed on it. The exterior, of which alone I am speaking, has not a single detached column about it, and is, therefore, deficient in relief.

This church has been overpraised both by Byron and Lamartine, the latter more extravagantly when he says that in St. Peter's Church Michelangelo has clothed the idea of God with all the beauty of which it was capable, which is not true. The front of it was susceptible of such treatment by means of colonnades as would have rendered it infinitely more beautiful. Never was the homely proverb, "Too many cooks will spoil the broth," more strikingly verified than in the design of the Pontifical Church of St. Peter. The least eminent of the architects employed on it ought to have produced a superior principal façade, which lacks those mighty and vigorous masses of shadow without which, as Ruskin justly remarks, no building can be truly great.

Great mistakes, I grant, may be attributed to many of the leaders of the movement, and to none more than to him whose name has become identified with Italian architecture,—Palladio, who, it is certain, has been over-estimated by many eminent critics, as Quatremère de Quincy, Hope, Beckford, and, strange to say, by the great poet and philosopher, Goethe, who represents him as ever seeking to embody some "great image which he carried in his soul," a scarcely correct notion of architectural generation. He too often forgot that the beautiful in architecture springs out of the useful, having left instances among his works of unbordered windows, and of the columnar order constituting the whole of the architecture, which could, therefore, be separated from the building, though the better principle had been exemplified in the Florentine school. Palladio, however, oftener pursued architecture in the right spirit, and has left works, in the true sense of the word, original. He had no notion of merely reproducing Roman buildings, nor even adapting them to his purposes, but strove to mould the antique elements into accordance with his own ideas. He seems to have begun his career with the persuasion that the style would stoop to the humblest purposes of life, and that in extending it to such he was only continuing the applications of their architecture begun by the ancients themselves. His predecessors probably considered it as fitted only for churches, palaces, and public buildings; but Palladio's varied works at once proved that its applications were unlimited.

But be his faults or mistakes what they may, they are no reproach to the style which was practised in his time, the productions of which, in not a few instances, while they are unlike any former works, and therefore original, are amongst the most successful structures ever reared for harmony and beauty of form, and refinement and elegance of detail; being the issue of a fruitful imagination under the guidance of a pure taste and sound judgment.

Brighter and more enchanting forms than any that have yet appeared may be embodied by it, brought from among the golden visions that lie mirrored in the fairyland of the imagination; especially of the gayer and more aërial kinds, which will be admitted by him whose eye, bodily or mentally, has ranged over the creations of a style which is an offshoot of it,—the Saracenic,—in various countries of the East, more especially the exquisitely lovely scenes of fairy splendour in Hindostan, which are frequently aided in their designed character by a material of such purity and brilliancy that the whole resembles a flood of moonlight.

More artistic and higher combinations of Greek and Roman elements than Palladio or his predecessors or followers thought of are possible, and, what is more, are really called for by utility in some of the highest class of works. The great defect of the trabeated system is, that it is only fit to form the façade of a building to be entered singly, or in single file, and will not form the lofty and broad entrance required by a palace or church, for processions, without injury to its beauty; and while the colonnade is necessary to the highest grandeur, the arcade is essential to a great entrance-door or gateway. It gives the largest single opening,—an opening as broad and high as can be required.

But I believe the two principles can be combined in the formation of a grand entrance consistent with artistic harmony and unity; that is to say, two colonnades may, with some careful management, be combined by means of a connecting archivolt springing from entablature to entablature, into one great and harmonious feature, embracing a central entrance, which may be as great and lofty as could be desired. The side intercolumnar spaces would be subsidiary entrances, and highly useful and pertinent; or, where not required for entrances, would form framework for sculpture. The breadth of entrance thus secured seems highly desirable in any public building, whether public processions are to be provided for or not; and the mode of obtaining it here suggested is worthy of consideration for its increase of combined fitness and beauty. It would be a new kind of coalition between the Greek and Roman or Romanesque styles.

The Italian style as it spread from Florence, where it rose, to Rome and Naples on the south, and to Venice, Genoa, and Milan, on the north, accommodated itself to the natural, political, and social peculiarities of each city; most notably to those of the sea-girt and sea-intersected Venice, and so became the chief ornament of that gem of cities. It showed it could breathe a still more northern air, that of England, wherein a few works could be found that, for purity, harmony, and appropriateness, will compare with any of a corresponding class in Italy; along with abundant proof that no elements will so satisfactorily weave into the continuous houses or shops we require in our streets, with regard both to convenience and beauty. Indeed, its merit and value lie not in its sageness and beauty only, but in its organic vitality and possession within itself of the principle of future expansion and application to all the multiform and accumulating demands of human life. It will as truthfully form the features rendered needful by rain and wind and cold as those required by sunshine and heat; in other words, it is a Northern as well as a Southern style.

It will, doubtless, form in perfection every species of public and private edifice called for by the various institutions of every country of Europe, including engineering buildings, bridges, viaducts, &c., along with strictly architectural ones, without sullying its Classic purity, and render them musical as is Apollo's lute; for those columnar elements are susceptive of the utmost grace and refinement of which structural art is capable.

Such failures as the exterior of the British Museum are no disparagement of the style, for that is a magnificent display of its elements, which, owing to timidity, or want of imagination in the architect, were not worked up into a design. It is not answerable for that, nor for another remarkable instance of undigested material, which, in justice to architecture, should be pointed to, viz., the new Houses of Parliament at Vienna, a view of which was given some four years ago in the *Builder*, and now, I presume, approaching completion; which is nothing more than a number of decorated blocks of building in mechanical conjunction, which, though forming a magnificent architectural group, have no claim to be considered a work of art.

Nor are those modern buildings, which are externally reproductions of the Greek peripteral temple, such as the Town-hall at Birmingham, the Church of the Madeleine and the Bourse at Paris, the Walhalla at Bavaria, to be considered as anything but libels on the character and resources of the style, which is capable of infinite variety on the Greek type, and greater display of columnar richness and grandeur. The periptery, unless redeemed by Parthenon-like perfection of line, by variation of capitals in the same façade, and high-class sculpture in the pediments and friezes, is a monotonous spectacle. Klenze in the Walhalla could have produced a national temple that would, in point of composition, have been an advance upon it.

What in each country this style requires is to be made as much as possible to form, not adorn merely, windows, doors, porches, chimneys, and other features required by the climate, in emulation of the Gothic, which grew up and around,—identified itself with,—essential features, as in the window, which was the most useful feature, and became the most beautiful, the useful and beautiful growing up in conjunction; which must be always the most pleasing, like that rarity a virtuous mind in a beauteous body. As to the chimney, it seems a providential provision for relieving the sky-line, and giving intimation without of the home-life within.

The so-called Queen Anne movement, in search of greater picturesqueness, seems to me to be uncalled for. Holland is useful to feed the imagination of the architect, which must ever be indebted to reminiscence,—a fact the ancients meant to indicate by representing the Muses as the daughters of Memory. Inspection of the picturesque buildings of Holland is calculated to make his own mind more prolific. They are seed cast therein to bear fruit in his own works. But with the highest reverence for the art-genius of the Dutch of the seventeenth century, (most brilliantly manifested, however, in painting), I think it is unworthy of English architects to introduce and set up here a style from Holland. It is, to say the least, going to the

huckster's shop instead of the warehouse for our provisions.

If we are as truthful and independent in our treatment of the columnar architecture, in acclimatising and nationalising it, as were the Dutch architects, and withal pay due attention to the securing a good and lively outline, and light and shade in designing, and are careful ever to make a beauty of necessity, we shall be sufficiently picturesque. Time and weather, and accident are agents in the production of that extreme degree of picturesqueness which the landscape-painter delights in; and their effects are not to be anticipated by the architect.

When I contemplate the beauty and capacity of the style in question, and of the styles descended from our forefathers in their respective embodiments,—the result of the highest efforts of the wisest nations in the way of architecture, forming a mine of elements such as neither Greek nor Roman ever knew, and put into the hands of all by means of engraving and photography, I feel more disposed to exclaim, in the words of the Psalmist, "The lines have fallen to us in pleasant places, and we have a goodly heritage," than to complain of the want of a national style. For if these are not our national styles whose are they? A question history is best able and has most right to settle, and she intimates, I think, clearly that in working in an adapted or modified Italian style we are truly succeeding and following the great nations that have preceded us in civilisation,—Egyptian, Etruscan, Greek, ancient and modern, Roman, Venetian, Pisan, and Florentine,—in the way we should go,—the providential way, with increased and accumulating means and opportunities of arriving at successful issues. Our difficulty seems to me to be not in having no national style, but in having two national styles,—the style we inherit from Classic antiquity along with its civilisation, and that bequeathed by our forefathers,—a style to which many hearts cling, and not without cause. We have two phases of architecture, so beautiful that we cannot turn our backs upon either, and may say, in the words of Gay's "Beggars' Opera":—

> "How happy could I be with either,
> Were t'other dear charmer away!"

and I question whether any former nation would not have felt and acted in like manner.

If the Gothic would borrow a little more of Greek refinement from her Oriental sister, the Byzantine style, of which she is highly susceptible, and fully recognise the change in the world and in her own circumstances since she fell asleep in the sixteenth century; and if the Classic at the same time were fully nationalised, they would assimilate so far that there would be but little discord in our towns arising from the pursuit of both.

Whether they would or not, neither Gothic nor Classic can ever be abandoned in favour of a new style; for no new style will ever be invented or generally followed. We had better, therefore, accept that fact, and pursue the styles we have, which, indeed, seems the providential course. Each style, however, should have its separate followers, as no man can with heart and soul follow both; and the student should be taught to make choice of one or the other, which would be most favourable to his growth in artistic feeling and power. It was, therefore, wise in the Royal Academy Professor in his recent lecture to discourage the following a plurality of styles. Inigo Jones was, doubtless, right in appending a Corinthian portico to old St. Paul's Cathedral. He could put some feeling into that, but he could probably have put none into a Gothic porch, and a living dog is obviously better than a dead lion.

I conceive of architecture, like the graceful figure of her on the tomb of the Italian architect Sada, engraved in the *Builder* not long ago, as flourishing in the bloom of an immortal youth and beauty,—for such the rose of juvenility must intimate on the brow, pensive though it be, of a lady who, if her first advent on earth was in Egypt, and the sanctuary of Karnach was her firstborn, must be over 4,000 years old. I grant that she has betrayed great eccentricities within the last century, not only in England and the North, but in Italy, the birthplace of her most illustrious modern followers. But I strongly suspect that her aberrations are in a great measure owing to the conflicting opinions and advice of her councillors (the critics), whose utterances have been, in too many instances, merely empirical, and too seldom based on the spiritual and emotional nature of architecture and art. Instead of trying to breathe into her some sparks of her ancient fire, by reminding her of her glorious antecedents and achievements, and especially of her labours of love in ancient Greece and in Mediæval Europe, through which she has helped the cause of civilisation in the world, and even exalted the idea of religion, they have of late been prophesying evil against her, insinuating that she is in a decline, and all but defunct; one, otherwise an eloquent and judicious critic, even talking of mourning in sackcloth and ashes over her degradation. A glance over the chart of her history will show that she is, like ourselves to a great extent, the creature of circumstances,—the sport of accident; and if so, surely no circumstance, no accident, can be more injurious to her than such conduct on the part of her friends, concerning whom she might well, with the ancient Roman, cry out to the Gods, "Oh, save me from my friends!"

What she has once done she can do again. The aliment on which she lives is as nourishing and the fountains of her inspiration are as lofty as ever they were, and more unfailing. Of a soul-born, spiritual substance, she is necessarily indestructible, and exempt from the common lot of obsoleteness:—

> "Age cannot wither her, nor custom stale
> Her infinite variety."

Like her sisters, Poetry, Painting, and Music, she has fresh fields and pastures new and delightful for ever stretching out before her, through which she may

> "Still walk in beauty like the night
> Of cloudless climes and starry skies."

But I have long been of opinion that her gait and mien would be more majestic if she were not so much perplexed with matters which do not properly belong to her, and which might very well be intrusted to another and more material agent, called Practical Building or Construction, who would be held responsible for the faithful and durable embodiment of her images of beauty. She should be on intimate terms with, nay wedded to, Constructive Science, and her conceptions should be the fruit of the union; but beyond the full mental development of every part of her offspring as to form and hue in all their minutiæ, she should not be expected to operate. All the rest ought to be left to her deputy or subordinate, Practical Building, educated expressly for the post, who should govern and direct his invaluable servants,—Masonry, Bricklaying, Carpentry, Joinery, Plumbing, &c., and become answerable for their honest service. I do not mean that she (Architecture) should shirk any mind or heart work whatsoever, but simply relieve herself of all that is merely mechanical, and that could be as well or better done by another, and reserve her strength for higher work.

I know nothing more that is wanting beyond what I have directly or indirectly pointed out to render her winter of discontent a glorious summer but sincere and earnest followers who, like Michelangelo, would work for the love they bore to her, and not merely for the gold they could wring from her. Some gold they must have, and some gold she will doubtless give them, but the "accursed thirst of gold," as the prince of Latin poets calls it, must not be their inspiration. It is not too much to say, "We cannot serve her and Mammon," a truth which it is important for those who have her interest at heart, and are anxious to remove all stumbling-blocks from her path, to bear in mind. A community of her true followers, wheresoever born, bound together by sincere attachment to her for her own sake, would constitute the true modern Freemasonry, and be a worthy successor to the Mediæval; the proper successors or continuators of the Freemasons being surely architects and skilled and scientific builders, architectural sculptors and carvers, and even earnest foremen and workmen, rather than the miscellaneous fraternity (miscellaneous as regards individual professions) that now bear the name.

Than such a community of various ranks of earnest men, each pledged and incited by every high consideration to the service of their beautiful mistress, through evil report and through good, nothing, I think, would be better calculated to meet the present exigency, and awaken in the profession, or at least in the breasts of all susceptible of it, some sparks of the pure religious-and-art spirit under which the Mediæval Freemasons worked; while the achievements of the Freemasons, and Greeks, and Italians,—that is, architecture in its highest examples and possibilities,—would be likely to seize upon and enflame their imagination, and become an ideal standard of aspiration. Such an institution would, like chivalry, have a purifying and elevating influence on the character of each member.

Within such an institution I can imagine the workman sympathising in the emotions of the architect, and having an æsthetic part in the adornment of his works.

Samuel Huggins.

SANITATION IN ANCIENT ROME.

As we pointed out in a recent article* on the architecture of modern Rome, there is every probability of Italian art becoming a thing of the past, especially if, as seems to be the case, the deterioration so noticeable on the Tiber should extend itself from one end of the Italian Peninsula to the other. Modern Italian architects and artists appear to be far behind their glorious predecessors, who have made their works serve for imitation to many generations of artists. But modern Italians have also deteriorated, compared with their forefathers, in other domains of what constitutes civilised life. This remark applies especially to the question of sanitation. We know, at least travellers very often do to their cost in the loss of health, that in sanitary matters Italy does not occupy a very high place; and from a lecture recently delivered by Professor Uffelmann, of Rostock, it appears that in this respect they are not nearly on the level occupied by the ancient Romans. To do them justice, however, it ought to be added that, for that matter, they are no worse than other nations, who very often are behind their ancestors in a good many things, and might well learn from them. At present, however, we have only to deal with Rome; and from the lecture to which we have referred, and which throws much light on a subject hitherto very little known, it appears that in ancient Rome, the metropolis of former times, there existed important institutions for preserving health amongst its inhabitants.

Although there were then at Rome no sanitary inspectors, in our modern sense, the Ædiles and Censors were charged with sanitary functions. It was the Emperor Augustus who first appointed inspectors of water-supply and superintendents of sewers, who exercised a sort of police supervision also over the river of the city, the Tiber. The city of Rome was early provded with a system of sewers, which at first, at the time of King Tarquinius Priscus, only had the object of draining some parts (amongst them the Forum) of the city, but which later likewise served the purpose of modern sewers, that of receiving and carrying away all descriptions of refuse. Under Tarquinius Superbus this system of sewerage was completed by the construction of the Cloaca Maxima (the largest sewer), leading to the Tiber, which still exists, and, whatever be the difference of opinion as to the provision of large sewers, may well rank with the best sewers of our time, so far as regards excellence of construction. For five centuries this system of sewerage was carefully preserved, extended, repaired, and cleaned. But with the decline of the city this great work was permitted to fall in ruins, and only the principal sewer remained, which has been preserved down to our day, but choked up by mud, and at its end towards the Tiber filled up to two-thirds its height.

The second fundamental condition for the preservation of the public health, that of providing the city with an abundant supply of good water, was done full justice to in ancient Rome. When the water in the Tiber, in consequence of its contamination by the population inhabiting its banks, could no longer be used for drinking, the Censor Appius Claudius constructed an aqueduct, for the greater part underground, from Praeneste to Rome, which called after him the Aqua Appia. Fifty years later this was supplemented by a second; and, after other seventy years (144 B.C.), by a third aqueduct, the Aqua Marcia. The latter brought the water from the Sabine Mountains, was thirty-two miles long, and supplied excellent water, which for centuries refreshed thirsty Romans, and which was originally constructed at a cost of 2,000,000*l.*, an enormous sum at that time. It was in ruins for many years, but

* See p. 288, *ante*.

was restored ten years ago, and has since then furnished Rome with its water supply. Numerous other aqueducts, some of them very magnificent and gigantic, were built. Towards the close of the Empire, nineteen aqueducts, fourteen larger and five smaller ones, conducted the water to the metropolis. At the end of the first century after Christ, ten aqueducts supplied a daily quantity of 33,000,000 imperial gallons of water to Rome. As four-eighths of this volume were used by the Thermæ, or public baths, and one-eighth by the imperial palaces, there remained yet three-eighths for the use of private consumers, the quantity supplied to the two million inhabitants of the metropolis being sixty-two imperial gallons of water per head per day for domestic use. The water was conducted through the city in leaden or earthenware pipes. The aqueducts were fully protected by law. No buildings could be erected over them, no trees planted near them. Heavy punishment was inflicted on persons polluting the water or damaging the aqueducts or conduits. With the decline of Rome, those splendid institutions also fell into ruins; but they were partly destroyed by hostile armies or besieging forces, in order to compel the Romans to surrender their city.

Public baths reached a state of perfection in Rome such as has not been attained by any other nation. At first, of course, only the Tiber formed a natural basin for ablutions; later artificial public baths were constructed, and under the emperors the Thermæ were introduced. Those magnificent bathing establishments not only furnished cold, warm, and hot baths, but they supplied also shampooing baths and cold ablutions; anointment of the body was likewise practised there. Those institutions still serve in many cases as patterns for baths erected now for our well-to-do classes, but which at that time existed in incredibly large numbers, the use of them being, besides, free to all comers. But those establishments did not bring with them the unmitigated advantages it was probably at first thought they would furnish; they degenerated, and became the abodes of idleness and hotbeds of vice.

There was no want of regulations in ancient Rome as to height of houses and width of streets. When, after the great fire, under Nero, the city had to be rebuilt, regulations of this description had to be strictly followed. There was likewise an abundance of public places of amusement, walks, and public gardens. The government also looked to the supply of provisions, its solicitude at first being merely confined to taking care that a sufficient quantity of corn was continually stored in Rome. Many descriptions of food,—for instance, meat,—were also inspected. Of the stored grain, large quantities were given away to the poor since the time of Cæsar; during the reign of Pompey very nearly 1,000,000*l.* was spent for this purpose annually.

There existed many charitable institutions, although there were few of them according to our notions. The Emperor Nerva sank large funds, the interest of which was applied in supporting the children of poor parents and orphans. Trajan placed nearly 5,000 children on the list of recipients of corn. Antonius Pius founded an institution for poor girls. Hospitals did not exist very early; they sprang up under the influence of Christianity, their number amounting in the ninth century to over twenty. Nothing was done in the direction of public care for the poor until the middle of the second century after Christ. Antonius Pius appointed communal physicians, who were free from taxes, but who were under the obligation of rendering certain services to the state and the commune, and who had, among other things, to treat gratuitously all the poor of their respective districts. Alexandrus Severus was the first to pay them a salary, and gave them the name of *Archiatri populares*.

The ancient Romans did not permit the industrial classes to poison the air for them. Fullers, who used urine in a state of putrefaction in the manufacture of cloth, had to carry on their calling outside the city gates or in its remote quarters. Roman law-makers had a watchful eye on the disposal of the dead. At first deceased persons were interred inside the city; later those interments were prohibited, and a public cemetery was laid out outside its walls. Funeral funds existed very early in Rome, which paid, as in our time, a fixed sum at the death of a member if the latter had subscribed regularly. Cremation was introduced in the time of the Decemvirs, at first only in the case of individuals, but later, after Sulla, cremation became more common. At one time this was the general mode of disposing of the dead, but committal to the soil was never entirely abandoned, and with the spread of Christianity became again more general. But in the beginning of the second, during the third and fourth, and the beginning of the fifth centuries, the Christians used the subterranean cemeteries, the so-called Catacombs, in which the bodies were placed in hollows cut in the walls of the passages driven through the tufaceous limestone underlying Rome, the cavities being afterwards closed by marble slabs, on which the names of the deceased were engraved. In time these catacombs became more and more complicated.

From the above it will be seen that the institutions and hygienic regulations of the ancient metropolis were very remarkable, and in some respects at least much more perfect than at the present day in many cities and towns the inhabitants of which think a great deal of their sanitary arrangements.

THE ROMAN CAMP OF BONNA ON THE RHINE.

The excavations which have been carried on very quietly near Bonn, at the expense of the Provincial Museum of that town, and under the direction of Dr. E. aus'm Weerth, and which had the object of laying bare the Roman camp of Bonna, established a short time before the beginning of our era, have been crowned this year with well-deserved success. With the assistance of Herr Koenen, sculptor, of Neuss, and one of the editors of the *Organ für Geschichte und Alterthumskunde von Düsseldorf und Umgegend*, the above-named explorer has, within a comparatively short time, succeeded in exposing not only the complete remains of the *Porta principalis sinistra* and parts of the enclosure-wall joining on to it, but also the remains of the *Porta principalis dextra* and remnants of the *enceinte* forming the eastern boundary of the camp. Owing to his exertions, full light has now been thrown on the position, camp form, and arrangement of this great military station. It formed a square with sides 1,706 ft. long and rounded-off corners, and was surrounded by a wall 6 ft. thick, a ditch 56 ft. wide, and an outer rampart of a width of 29 ft. 6 in. A rampart, 29 ft. 6 in. thick, abutted on the inner flank of the enclosure-wall, along which, for the whole circumference of the camp, the *Via angularis*, 18 ft. wide, could be traced. Besides this road there were three others, the *Via prætoria*, the *Via principalis*, and the *Via quintana*. Each of them terminated at either end in a corresponding gate. These gates were,—the *Porta prætoria*, which lay close to the Rheindorferweg, close to the south-east corner of the Jewish cemetery; the *Porta decumana*, found in the same line, south of the road "An der Esche" (north of the Rosenthal); the *Porta principalis dextra*, which was laid bare on the Viehweg, in front of the Wichelshof; the *Porta principalis sinistra*, discovered in the same road, east of the Rheindorferstrasse; and, finally, the remains of foundation, probably, of a northern tower, forming the termination of the *Via quintana*, on the road leading to the Rhine between the Viehweg and the Rosenthal. The *viæ* of the castrum are bordered by large buildings, of which several have already been disclosed, as well as a complete system of canals. The arrangements of the various parts of the camps show that it was a military station of the first rank. For instance, no *Porta principalis sinistra* has hitherto been discovered which can compare in size with that of Bonna. It is a double gate, of about 26 ft. wide, flanked by two heavy square towers, each 37 ft. 6 in. long, and 29 ft. 6 in. wide, and the enclosure wall abutting on to them on their outside. The several walls have partly a thickness of about 7 ft. The material used for them and the other structures of the castrum is tufa. Professor aus'm Weerth must certainly be congratulated on the completeness of his archæological discoveries, doubly interesting on account of their close connexion with the history of the civilisation of the Rhine country, which may be said to have commenced with the Gallo-Roman and Germano-Roman campaigns. A hope is expressed that further means will be supplied for completing the investigations which have been so successfully carried on thus far.

THE HOLLOWAY COLLEGE, EGHAM, SURREY.

Not far from the Virginia Water Station of the London and South-Western Railway, two remarkable establishments are in progress of completion at the cost of Mr. Thomas Holloway, and which he proposes to present to the nation. Including endowments and fittings the expenditure will be little short of a million sterling,—certainly a noble gift. One of these is a Sanatorium, for curable cases of mental disease,—a building already partially illustrated in a previous volume of the *Builder*. The other, at some little distance from the Sanatorium, in the direction of Egham, is a college for the higher education of women; and of part of this we give a view in our present issue. It stands in an area of 95 acres of freehold land at Mount Lee, and has a frontage to the high road of about three-quarters of a mile, close to Windsor Great Park. The college buildings, already far advanced, are set back from the road upon an elevated plateau commanding a superb view of the surrounding country, and surrounded by pleasure-grounds, extensively planted and intersected with groves, streams, and lakes. The designs for the construction of the building, approved by Mr. Holloway, were made by Mr. W. H. Crossland, architect, who is now superintending their execution. The style is that of the French Renaissance, in which sculpture enters largely into the design, and here Mr. Crossland has had the able assistance of Mr. Fucigna.

Holloway College is of enormous size. It forms a double quadrangle 500 ft. from east to west, and 350 ft. from north to south. The main portions, which run from east to west on each side, consist of five floors, each 10 ft. 6 in. high, all of which (with the exception of the western portion of the lower floor, arranged as store-rooms) are rooms for students, professors, and class-rooms, connected by four spacious stone staircases placed equi-distant, two in each wing. The building is laid out to provide ample accommodation for 350 students, and each student will have two rooms, arranged as bed and sitting rooms, each 13 ft. 6 in. by 10 ft. 6 in., and divided by corridors 10 ft. wide and 500 ft. long on each floor. The professors and heads of departments will have rooms in the central and corner pavilions, which are slightly larger in area. There are three class-rooms also in the corner pavilions, each 28 ft. by 16 ft. on the ground floor, together with a lecture-theatre, 42 ft. square by 18 ft. high. The three cross buildings running from north to south have been arranged as follows:—That on the west front comprises the chapel, 130 ft. long by 30 ft. wide and 30 ft. high, and a recreation-hall 100 ft. long by 30 ft. wide and 30 ft. high. These two apartments have a spacious driving gateway between them, carried up through two floors, and leading into the upper or western quadrangle. The gateway is surmounted and surrounded by suites of rooms for chiefs of departments, arranged five on each floor, with porters' rooms, &c., all approached by stone staircases, the whole being crowned with a clock tower, rising to a height of 130 ft. from the ground.

The cross building between the two quadrangles will contain on one side the dining-hall, 104 ft. by 30 ft. by 25 ft. high, and on the other side the kitchen, 80 ft. by 30 ft. by 25 ft. high, together with cooks' rooms, stores, and surgery, &c. The centre between dining-hall and kitchen is occupied by an octagonal tower, 100 ft. high, containing on the ground-floor a central hall 35 ft. in diameter, approached from each quadrangle by flights of steps, as well as from cloisters and the terraces over them, which run the whole length of this building on each side from north to south. The upper part of the octagonal tower above the roof-line contains two series of low-service cisterns for supply to main buildings and hydrants. The floor under the dining-hall is laid out as servants' rooms, and that under the kitchen as stores, with large entrance-hall between, entered from either quadrangle. The cross building on the east front, also running from north to south, contains, on the lower floor, the tradesmen's driving gateway in the centre, 48 ft. by 17 ft., on the left of which is a gymnasium and racket-court, each 50 ft. by 30 ft. by 16 ft. high, with lavatories, &c., adjoining, with library on the floor over 100 ft. by 30 ft. by 30 ft. high. On the right of the gateway will be two large music practice-rooms and twelve small piano-rooms, with museum and picture-gallery on floor over, 100 ft. by 30 ft. by 30 ft. high. The

driving gateway in the centre of this block will have suites of five rooms on each floor over for heads of departments, reached by a spacious stone staircase, and the whole surmounted by a bell-tower 140 ft. high. The three cross buildings are approached from the main buildings at each end as well as from the quadrangles, cloisters, and terraces in the centre.

The contract with Mr. John Thompson, of Peterborough, was signed on the 30th of July, 1879; and the building has now been in course of erection for two years, and rapid progress is being made, the contractor having agreed to have the whole finished and delivered up in four years from that date for the sum of 257,000*l.* This amount is exclusive of fittings, furniture, &c. Extensive plant and machinery are employed on and about the works, and about 800 men are constantly at work.

The constitution of the college, to be embodied in a trust-deed or charter, will set forth that the college is founded by the desire and counsel of the founder's wife, now deceased, and that its object is to afford the best education suitable for women of the middle and upper-middle classes. The trustees are to be a corporate body, with perpetual succession, and to have all the usual powers and privileges. The governing body will consist of twenty-one persons, to be appointed partly by the University of London and partly by the Corporation of London, and it is stipulated that a certain portion shall always be women. Religious opinions are not in any way to affect the qualification for a governor. It is the founder's desire that power by Act of Parliament, Royal Charter, or otherwise, should be eventually sought to enable the college to confer degrees after due examination; and that until such power is obtained, the students shall qualify themselves to pass the Women's Examination of the London University, or any examination of a similar or higher character which may be open to women at any of the existing universities of the United Kingdom. The curriculum will not be restricted to subjects enjoined by any existing university. Instead of being regulated by the traditions and methods of former ages, the system of education will be mainly founded on studies and sciences which the experience of modern times has shown to be most valuable, and as best adapted for the intellectual and social requirements of students. The governors will, therefore, be empowered to provide instruction in any subject or branch of knowledge which shall appear to them, from time to time, the most suitable for the education of women; and the curriculum of the college will not discourage students who may desire a liberal education apart from the Latin and Greek languages. Proficiency in classics is not to entitle students to rewards of merit over others equally proficient in other branches of knowledge. It is intended to provide twenty founders' scholarships, of the value of 40*l.* each, tenable for not more than two years in the college. No professor will be required to submit to any test concerning his or her religious opinions. The founder declares that, "having witnessed the hand of God in all things," it is his earnest desire that the religious teaching of the college should be such as to impress most forcibly on the mind of each student her individual responsibility, and her duty to God. Students will have the right to attend the services of the Church of England, or of any sect or denomination which their parents or guardians may desire. The domestic life of the college is to be that of "an orderly Christian household," with a daily simple service, the reading of a portion of Scripture, and a form of prayer approved by the governors. The Principal of the college will be a lady, and duly qualified lady physicians and surgeons are to be resident in the college. Other important articles in the proposed constitution of the Holloway College are that the lady principal shall, with the sanction of the governors, make from time to time, such provisions as might be expedient for the conduct of public worship on Sunday in the college chapel, but no permanent chaplain shall be appointed, and no arrangement shall be made which would identify the college in any way with any particular sect or denomination of Christians; that no other church or chapel, or place of worship, shall at any time be built on any part of the college estate, as a very large, handsome, and suitable chapel, with a fine organ, will be provided in the college building; that all the students shall reside in the college; that no house for any professor, teacher, chaplain, or minister, shall now or hereafter be built on any part of the estate; that no student who does not permanently reside, during the college terms, in the college, shall be permitted to receive instruction there. It is also provided that each student shall have for her separate use two rooms, which shall not be shared with any other student, and that students' residence at college shall be restricted to four years, unless, under special circumstances, an extension shall be sanctioned by resolution of the governing body. It has also been decided that no student shall at any time be admitted to the college who has not attained the age of seventeen, or who has not passed a satisfactory examination. The examination for admission shall be regulated from time to time by the governors, but shall, except as hereafter provided, never fall below the following standard:—The English language, composition, and history; the elements of Latin, French, or German, or some other foreign language; arithmetic, integral and fractional; the elements of some one branch of mathematical or physical science. Candidates who may have passed the senior local examination at Oxford or Cambridge, or the matriculation examination of the University of London, or such other examination by some competent and public authority as, in the judgment of the governors, is equivalent to such University examinations, shall be admissible to the college without further examination. Provided always, that during the first seven years after the opening of the college, the governors shall be at liberty, in special cases, to relax the above-named conditions, and to make such regulations for the admission of students as they deem expedient. The lady principal is endowed with almost absolute power, subject to the approval of the governors, but she also must conform to sundry regulations. She must not marry, on pain of disqualification; and on attaining the age of sixty she must resign, like all other professors in the college.

Mr. Holloway, amongst his other good works, contemplates the formation of a picture gallery in the college, and the paintings he has already purchased for the purpose show that it will be a collection of no common kind.*

The illustration we give is a reproduction of a drawing exhibited recently at the Royal Academy by the architect.

THE TOMB OF PRINCE JOHN.

Prince John, second son of Edward II., was born at Eltham, in Kent, on Ascension Day, 1315. The year after his father's assassination he was created Earl of Cornwall by his brother, Edward III., at a Parliament held at Salisbury.

In the year 1333, a proposal of marriage was made between him and Joan, daughter of Ralph, Earl of Eu, and in the following year another with Mary, daughter of the Count of Blois; afterwards a marriage was arranged with Mary, daughter of Ferdinand, king of Spain, in 1334, for which an agreement was drawn up; but the Prince did not live to fulfil the engagement, for in the month following, while in Scotland, he died, at St. John's Town, Perth, aged 19.

By the express orders of the king, he was to be buried *entre les royals*, yet so as to leave room for the king and his successors. This was fulfilled by his being laid in the quasi-royal chapel of St. Edmund, in Westminster Abbey. The body was removed with much pomp, and the funeral was so stately and magnificent that the then considerable value of 100*l.* was placed upon the horses and armour offered there on the day of his burial.

The tomb has a moulded base and panelled plinth of stone; above the plinth are panels of alabaster, each of which contained a small alabaster figure, with a dark back-ground, which Mr. Burges describes as slabs of black slate.

The cornice, with carved enrichments, is also in alabaster. The upper slab is of Purbeck marble, and the effigy is of alabaster.

In "Gleanings from Westminster Abbey," Mr. Burges describes the effigy as being "an exceedingly curious and valuable specimen of military costume. . . . . We see the curious garment, the cyclas, cut so much shorter in front than behind, then beneath it the gambeson, then the coat of mail, and lastly the haquetон.

The sword-handle is also very beautifully sculptured, and the shield is a very valuable example of heraldic drawing. . . . The little figures of weepers are open to the criticism of being placed in exaggerated attitudes, while the heads and hands are too large. The figures are all crowned and are excellent studies of costume."

In Neale's description of the tomb he says that the "effigy is in plate armour with a surcoat, a gorget, and a round helmet encircled by a coronet. The coronet of this earl is of the ducal form, viz, having alternately small and large trefoil leaves; he is said to be the first person whose coronet is so represented. On his left arm is a beater shield charged with his arms, viz., three lions of England, with a bordure of fleurs-de-lys."

The tomb was originally surmounted by a very fine stone canopy divided into three bays on each side by buttresses, which were carried up from the ground, terminated by crocketed pinnacles, the centre ones being higher than those towards the ends of the tomb. Each bay had a pointed arch with cinquefoil foliated cusping carved, and smaller secondary cusping, and was surmounted by a gable with crockets and figures as finials. Each tympanum was pierced by a circle with quatrefoil cusping and smaller cusping similar to the arch below; all the spandrels were also pierced and cusped. Upon the canopy and over the centre of the tomb was a pyramidal crocketed spire with angel figure as a finial. The soffit of the canopy was richly vaulted.

In the year 1775, at the funeral of Lady Elizabeth Percy, Duchess of Northumberland, the crowd that had collected to see the funeral was so great that the clergy and choir scarcely could make their way. Just as the procession reached St. Edmund's Chapel, the screen, together with a part of the canopy, of this tomb fell, bringing with them men and boys who had climbed on them. The confusion was so great that the Dean did not return to complete the service till midnight.

The canopy was wholly removed about fifty years ago by order of Bishop Pearce, then Dean of the Abbey.

My drawing represents the tomb in its present condition. W. B. Bassett-Smith.

OATLANDS SCHOOL, FOR WALTON-ON-THAMES SCHOOL BOARD.

The design for this building was selected in a limited competition including designs submitted by two other architects.

Accommodation is provided for 133 boys. The school-room is 57 ft. long by 20 ft. wide. The class-room is 57 ft. long by 15 ft. wide. Both rooms have open-timbered roofs. The master's house contains a living-room, 12 ft. by 12 ft. 6 in., with bay-windows; kitchen, scullery, and three bed-rooms over.

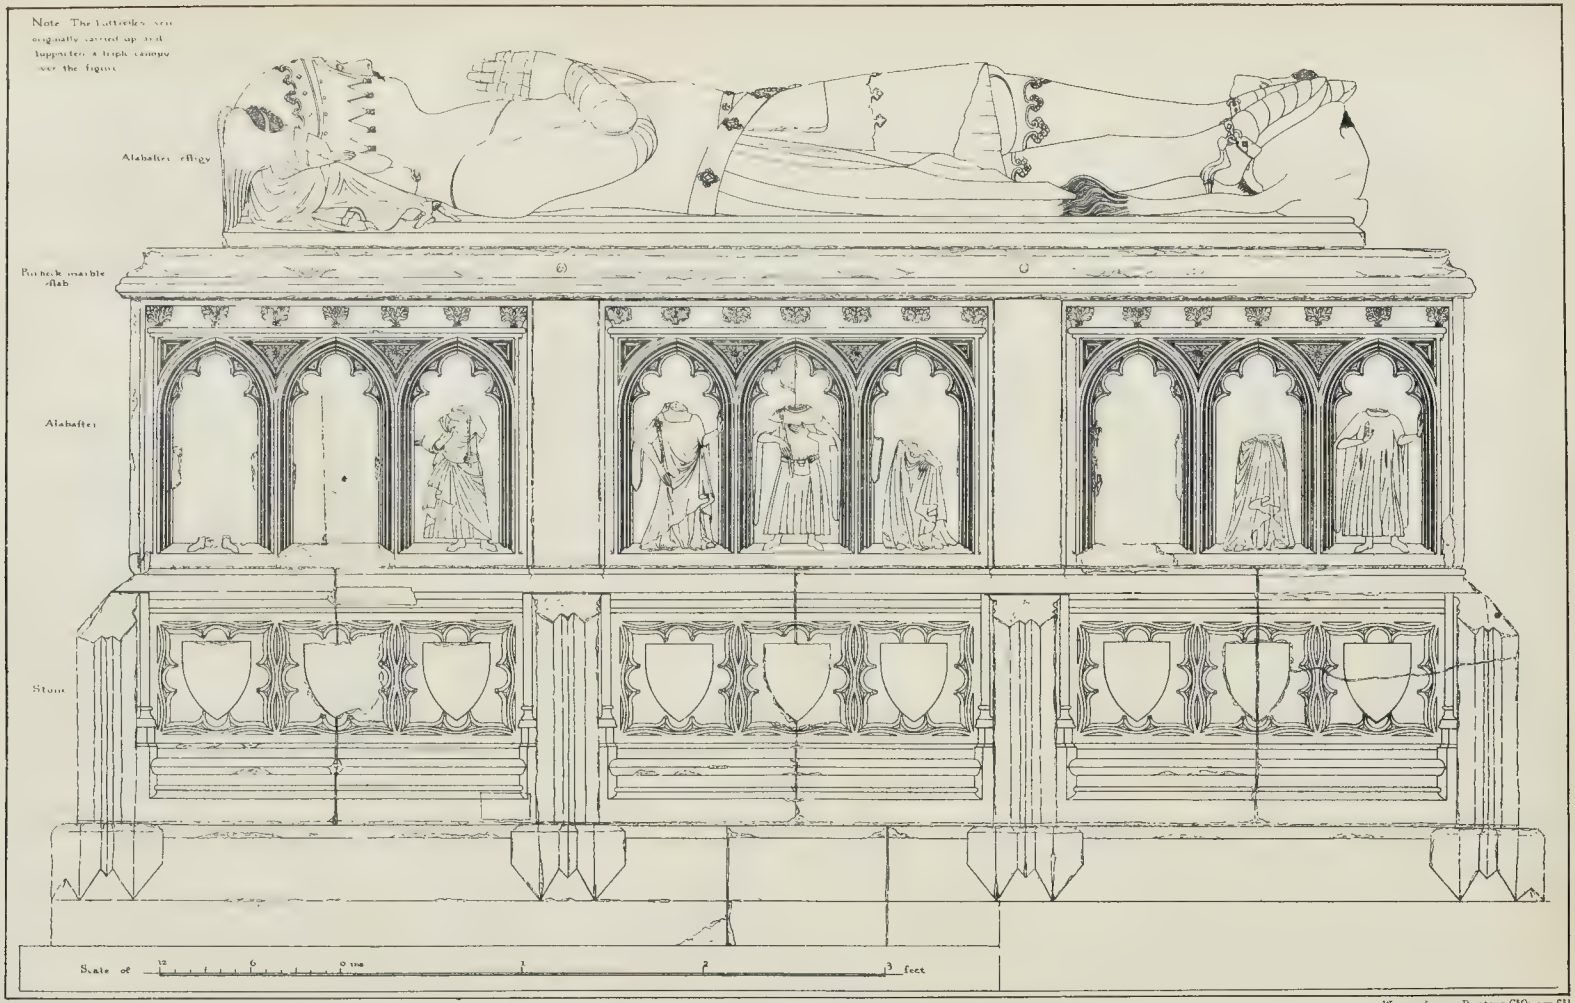
The school and class rooms are to be warmed by means of Mr. D. O. Boyd's hygiastic ventilating stoves. Ventilation is specially provided for by means of inlets in the angles of the rooms, and in each window-back; and outlets into an air-chamber in the roof; the upper parts of the windows also open.

Externally, the building will be faced with red Claygate bricks, relieved with timber work and tile hanging.

The roofs are covered with local dun-coloured tiles.

The contract has been taken by Mr. Frederick Peters, Jun., builder, of Oatlands Park, Weybridge, for the sum of 1,256*l.*

The architect is Mr. Rowland Plumbe, of No. 13, Fitzroy-square.



Iron and Steel Institute.—The reception committee have issued cards for a *conversazione* at the South Kensington Museum on Thursday, the 13th inst.

THE SOCIAL SCIENCE CONGRESS IN DUBLIN.

THE PRESIDENT'S ADDRESS.

Lord O'Hagan, in the course of the address with which, on Monday last, the proceedings of the twenty-fifth annual Congress of the National Association for the Promotion of Social Science were opened, spoke as follows in reference to Health questions:—

I pass on to tell you what has been done, since 1861, in a department not less important than any other within the range of your inquiries,—the department of public health. In that year Ireland had, as its chief sanitary authorities, expiring parish vestries, clothed with antiquated powers, which had been vested in them so far back as the year 1818. There were some other bodies acting for similar purposes, under statutes which had once had equal application to England and Ireland, but had continued in action here after they were repealed in England. Five years after the meeting of the Congress, in 1866, the vestries were finally abolished, and the guardians of the poor were entrusted with sanitary powers identical with those existing in England and Wales. The change was great and wholesome, and was pushed to better issues when the Local Government Board was created in 1872. It was armed with large authority, and acted with energy and success. An Act of 1874 developed the sanitary system and brought it into full operation throughout the country. Under that Act, the whole of Ireland was divided into sanitary districts, called urban sanitary districts and rural sanitary districts. The urban districts consist of towns having a population exceeding 6,000. The governing body of the town is made the sanitary authority. The rural districts consist of the poor-law unions, and the boards of guardians are the sanitary authorities. There are fifty-six urban sanitary districts, and 163 rural sanitary districts; and in each of those districts a complete sanitary staff has been organised under the orders of the Local Government Board. The medical officer of the dispensary district is, in all cases, the sanitary officer or medical officer of health. The principal duty of the sanitary authorities and their officers consists in the inspection of their districts, and in taking all necessary steps to compel the removal or abatement of nuisances, provide a proper supply of water, and construct, or cause to be constructed, where it may be necessary, proper sewers and drains. The Public Health Act of 1878 repealed all previous Sanitary Acts, re-enacting, amending, and consolidating their provisions, so as to comprise in one statute the entire sanitary law as it at present exists in Ireland. The principal subjects dealt with in the Act are:—

Sewerage and Drainage.
Scavenging and Cleansing.
Water Supply.
Abatement and Removal of Nuisances.
Lodging-houses.
Markets and Slaughter-houses.
Infectious Diseases.

So that the scope of the statute is comprehensive, as the machinery for effectuating its beneficial purposes is complete. I rejoice to say that its worth has been widely recognised. The increasing activity of the local authorities is demonstrated in the most conclusive way, by the amount of their expenditure for the last six years, as it appears in the audited accounts of the Board. I shall give you the figures, and you will judge how satisfactory they are.

Year.	Expenditure by Rural Sanitary Authority.	Expenditure by Urban Sanitary Authority.	Total.
	£	£	£
1875	32,934	25 933	58,867
1876	39,676	28,567	68,243
1877	44,870	29,185	74,055
1878	48,157	37,601	85,758
1879	50,767	31,312	81,079
1880	51,027	Not yet known.	—

But even more striking than this evidence of effort and progress is that which is afforded by the amount of the loans obtained from the Board of Works in those successive years, on the recommendation of the Local Government Board, "for objects, in the words of the Public Health Act, "which may be deemed sanitary improvements":—

1876-6	£37,584	1878-9	£124,454
1876-7	41,085	1879-80	285,179
1877-8	62,058	1880-81	199,252

It is not easy to over-estimate the importance to Ireland of the sanitary work which is thus proved to have been done. It has been of double advantage, by relieving the poor at seasons of sore distress, and securing the permanent improvement of the health of the community. Again, I think I may confidently say that in a department so deeply affecting the comfort and the happiness of a people, Ireland need not be ashamed of the progress she is making, and has made. And for her that progress is especially important. Health and social morals run closely together. Cleanliness and godliness are in alliance; and wholesome and commodious dwellings are important instruments of civilisation. The squalidness of his home drives the artisan for light and solace to the public-house. The mud-cabin, with its single room and crowded foulness, is not very compatible with the formation of ordered industry; and, save in a country still marvellously pure, its inmates would be subjected to many dangers. It is of great consequence, for reasons like these, which might be largely multiplied, that our sanitary work should extend not merely to lodging-houses, but, as far as may be, to the dwellings, generally, of the humbler classes; and that the English effort in that direction, which has been so happily prosecuted under the benevolent guidance of Lord Shaftesbury, should have wide and cordial imitation here.

I do not desire to take credit to your Association which it may not fairly claim; but you will permit me to mention, in illustration of the topic I have last considered, a not unpleasant reminiscence of 1861, of which record is made in the biography of one of our philanthropic citizens. In the autumn of that year, Mr. Senior and Mr. James Haughton resolved to give some practical application to wise suggestions which had been made as to the utility of ornamental gardening in public parks such as beautifies those of London, at the expense of the Imperial taxes. They prepared a memorial to the Executive. It was received with favour; and the People's Garden rose into existence,—at once a boon to multitudes who enjoy its beauty, and a worthy monument to the genial and accomplished Viceroy,—a true lover of the country he delighted to make his home,—whose graceful statue continues to adorn it.

And, touching thus on a local theme in connexion with public health, I may be permitted also to allude to the great undertaking by which, to the lasting honour of the man who conceived it and completed it, in spite of misconception and resistance, this city receives an abundant supply of pure water, secured by a vast but most profitable expenditure, which amounts, I am informed, up to the present time, to 530,000*l*. Nor should I forget to mention, in the same connexion, the gratitude which is due to a munificent nobleman who has lavishly employed his fortune in making one of the finest squares in Europe a place of joyous resort to his fellow-citizens. I can only make the briefest allusion to a measure most worthy of attention in the department to which I am referring,—the Irish Sunday Closing Act. It was hotly contested and violently denounced; but it has succeeded beyond expectation; and its moral influence in removing, even partially, the withering curse of national intemperance, has made it a practical reform of a high order. I cannot dwell on the mode of its operation; but the results are indicated in the most conclusive way by the unanswerable evidence of our criminal statistics. In 1878, when it was in action for a few months, the number of punishable cases of drunkenness was reduced by 3,000 as compared with the year 1877. In 1879, when it was in full force, the reduction was 11,000, and last year it was 22,000, the number of offences, which in 1877 was 110,000, having fallen to 88,048. It is not wonderful that success so signal, proved by these figures and in many other ways, should already have induced wise and good men to imitate the example of Ireland in other districts of the empire, with the sanction and by the authority of the Legislature. And does it not give us a fair ground for hope that the undoubted and most salutary improvement in the drinking-customs of the wealthier classes may be gradually extended to the multitudes beneath them; and that we may be emancipated, more and more, from the cruel dominion of a vice which is to us the perennial source of crime and misery, and degrades these kingdoms in the estimation of the world?

With reference to Art questions, the President said:—

Only a word as to our relation with the department you have lately added to your programme. The conditions of life in Ireland have not been, for many a century, consistent with the successful culture of the fine arts. They could not flourish in times, too much prolonged, of turmoil and misery and social chaos. We boast an ancient civilisation, which distinguished our island when darkness brooded on the world,—connecting the learning of famous seminaries, to which multitudes flocked from other nations,—*amandati in Hiberniam ad disciplinas*,—with excellence in art, still evidenced by the venerable ruins of our churches, and by remnants of rare workmanship in the precious metals and the sculptured crosses and rich illuminations of early Christian times, which have survived ages of strife and suffering, and are still to be inspected in our Irish Academy and in Trinity College. We are proud of their attestation to the old endowments of a country which in later days has vindicated its claim to artistic eminence by the great works of Barry and Maclise, and Hogan and Foley, and others who have gone; and of living men who inherit their genius and will emulate their fame. We have been placed at a serious disadvantage. The poverty of Ireland has not permitted a large patronage of art, and those who have been distinguished in any of its branches have found irresistible attraction and abundant reward in the English metropolis. But I am glad to be able to say that here, also, we have been making substantial advances. We have never, in later days, had such appliances and helps for the rising artist as we now possess. Our National Gallery, under wise and conscientious supervision, continually undergoing fresh development, need not shrink from comparison with similar institutions on the Continent. Its contents are very choice in their character and very comprehensive in the range of their subjects. A Science and Art Museum has been established, with every prospect of giving in a short time effective encouragement to art studies as applied to manufactures. Our Hibernian Academy was never so prosperous and so well endowed. Its visitors are increasing annually by many thousands, and, notwithstanding the hardness of the times, the purchasers of pictures become year by year more numerous and far more liberal in their expenditure. I allude to those things only that I may not omit all reference to our successful action in connexion with one of the most interesting of your departments; but I do not desire to intrude on the province of my noble friend who will preside in it, and more fittingly explain the nature and extent of the improvements to which I have lightly pointed.

In the Health Department on Tuesday,

Mr. Henry C. Burdett, F.S.S., read a paper on the desirability of hospitals being placed under State supervision, in which he adduced evidence in favour of this course being adopted. He said that a review of the discussions and circumstances relating to the management of hospitals and kindred institutions in the United Kingdom during the past five years, leads to the conclusion that hospital managers are becoming alive to the fact that the system heretofore in force cannot much longer continue unaltered and unreformed. During this period no less than four influential deputations have sought interviews with the Home Secretary, with the object in each case of obtaining a Royal Commission of investigation into the subject.

He placed first amongst the circumstances which have produced so active and unanimous a desire for inquiry the many anomalies of the present system of hospital administration. In the metropolis, especially, the hospital accommodation is imperfectly distributed, and in many districts is altogether inadequate. The administration of the hospitals as at present conducted is so uncertain and unsatisfactory that inquiry is needed to secure amelioration in the interests of the poor. To facilitate a right judgment, and to furnish reliable data, Mr. Burdett had prepared a variety of elaborate statistical tables. These showed that the cost of management in sixty-one general hospitals varies from 2½ per cent. at Cork, to 27½ per cent. at the Metropolitan Free Hospital; the cost per patient per week from 9s. 4d. at the Cork County Hospital to 3*l*. 0s. 4d. at the Leeds General Infirmary. A difference of 25 per cent. in the cost of management and nearly 700 per cent. in the cost of maintaining the patients, would alone warrant the appointment of a Commission. The special hospitals show equally startling discrepancies.

As to the distribution of hospital accommo-

dation, nearly nine-tenths of the bed accommodation in the London hospitals is situated within a radius of a mile and a half from Charing-cross. The population of London resident within the metropolitan area, and exclusive of the large number of persons who are annually sent to London for hospital treatment, cannot be less than four millions and a half, one-third of which number is annually relieved at the London hospitals. Out of a total of 4,579 beds for the whole metropolis, 3,486 are provided by the hospitals situated in the narrow area above specified. The unsatisfactory condition of the present out-patient system, and especially of that in force at the large metropolian hospitals, demands reform.

The appointment of a controlling authority, endowed with adequate powers to sanction, restrict, or prohibit the erection of a new or the extension of an already existing hospital or dispensary, was, he thought, urgently called for.

Nearly everywhere the building mania seems to have blinded hospital managers, so that extravagances, going far beyond the requirements of the districts in which the hospitals are situated, and entailing half-empty wards and increased cost of maintenance, are becoming the rule and not the exception. The indiscriminate institution of special hospitals and dispensaries is productive of evil, and a controlling power is urgently called for to prevent the multiplication of so-called charities, which oftentimes, springing from unworthy motives, decoy charitable funds from legitimate channels. Such examples of ill-advised expenditure reflect directly or indirectly great injury upon the poor, for whose benefit the large sums involved were originally intended.

The social and public aspects of this great question of the right government of our hospitals alone demand an immediate investigation. When something like one million and a quarter of the population of London annually seek and receive gratuitous medical relief, and when the whole wage-receiving class in the metropolis cannot be estimated at more than 1,400,000, there is enough to warrant an independent inquiry into the whole question by a Royal Commission. This feeling is rapidly spreading, and is making itself felt in the diminished incomes which the hospitals are now receiving from voluntary sources. This difficulty will certainly increase as the public become impressed with the knowledge that it is not the sick poor at all who are being benefited, but nearly the whole wage-receiving and industrial classes, a large proportion of whom are well-paid artisans.

ON THE REFINING AND HUMANISING INFLUENCES OF ART.

PERSEPOLITAN AND ROMAN PERIODS.

Under this title a paper was read in the Art Section at the Social Science Congress, on Wednesday, by Dr. Phené, F.S.A.

The author drew attention to the fact that, as in former papers, he had selected periods for comparison in which the national features treated of were either coeval or consecutive, and in which *contrasting* effects were most prominent, and as his object was to examine the influence of art in forming or swaying national character, the periods now selected exhibited *parallel* effects from similar causes, though at a greater interval, and with powerful intermediate nationalities, hence leading to more decisive conclusions. His last paper, on the Asiatic and Roman periods, might be supposed to have included the present one; but in that he had treated of Asian art during the time of the existence of high class art-schools, established after the period he was now considering. It might be thought that so little was known of Persian art, so little of Persian character, that there was but a slender foundation for evidence. That, he urged, was the evidence; the very little distinctive Persian art, and the flimsiness of Persian character, bearing a marked relationship. The Roman character was firm and vigorous, and the area of Roman arts extensive; but the parallel lay in the complete want of original art in both nations, and with the final similar result of annihilation. Indeed, the parallel was even more marked, for, in its earlier history, Persia assimilated to Rome in the primal temperance of its citizens and soldiers, simplicity of manners, dress, and customs,—through which both countries achieved their conquests and established their solidity, and at which periods in each art was unknown. Both also succumbed under a false appreciation of art, from its debasement to bodily and physical enjoyment, rather than the mental and philosophical refinements its culture produces, with their consequent far higher and more intense enjoyment. Although a momentary digression, he could give no better example than the following:—When it was sought to introduce the Asiatic mysteries into Greece, the Greek leaders long resisted them as degrading to the morality of the people. When it was sought to introduce the gladiatorial shows of Rome into Athens, a cry was raised by the populace, "First throw down the altar erected by our ancestors to Mercy" (Lucian).*

Here was true refinement from true appreciation of art; and it would be difficult to show that it proceeded from any other cause, as they were nations of a similar faith, and the Greeks even surpassing the others in military acquirements and courage, though numerically less powerful; while, of the three, they alone understood and cultivated art; they alone had artistic originality which taught them to reject alike sensual effeminacy from the East, and the cruel spectacular revels from the West. Greece and Greek fine art alone still live in fact; Rome and Persia but in history.

The effects upon existing nations have been widely different through the Asiatic and the Roman sway, notwithstanding their parallelism in deficiency of original art; for Rome had a period of utilitarian art, in which Persia was wanting. Both plagiarised to the fullest of their ability; both raised their palaces, and enriched their capitals, not only with the wealth, but the mental powers of the nations they conquered. The stupendous remains at Persepolis, combining the materials and dimensions used by Egyptian architects with the beautiful fluted columns and the capitals of quasi-Grecian art, attest this, though, with an Oriental supremacy and appropriation, the capitals were surmounted by an Indo-Assyrian ornament and shrouded with meaningless fretwork by Persepolitan artists, like the Eastern kerchief thrown over a captured beauty, to indicate that a place would be found for her in the harem. Even the gorgeous apparel of the Persians, and their costly tents and equipments, were borrowed from the Medes, the introduction of which by the great Cyrus was a folly of age inconsistent with his youthful chaste severity. When, satiated with conquest, and with the world at his feet, he resolved to fix his residence at subjugated Babylon,† he attired himself and his retinue, for the first time, in bejewelled and gold-embroidered Median robes, and with this was changed the retirement of the Persian women, who were thenceforward companions of the march and bivouac. The Persian is the effeminate feature of art.

The curious plan of Oriental enrichments on the sides of the great staircase leading to the celebrated hall of forty pillars at Persepolis, though having evidence of the Greek chisel, was also shown not to be original, but to have been borrowed from Chinese design.

Greatly different, the author pointed out, were the ruins of Rome, worked less in costly marble than useful brick, in which she stands pre-eminent. Her edifices tell, not alone of palaces, temples, and triumphs, but of aqueducts, factories, shops, and highways,—all borrowed from the Greeks of Europe or Asia, it is true; for Asiatic and Egyptian bricks, and (as we now know, from the recent discovery of that at Siloam) the aqueducts of the East, also existed before Rome was, but wonderfully adapted and beneficiently widely spread. At the very time that Rome was sinking from the influx of sensual luxury that came in with the spoils of Asia,—from her citizens not understanding the exquisite perfection and chaste purity of Greek art,—at that moment Western Europe was being enriched in utilitarian works by her paternal Government, soon to be polluted and withdrawn. But long as was the lapse and recoil into inactivity and darkness, those nations have recovered what she has not, and what Italy is now only slowly beginning to feel, a renascency, not only of all imparted by that great civilising mother, but with a picturesque and delicious charm arising from what Rome had not, the peculiar originality of each. So that whether in the useful or higher and refined art; in music, painting, or literature, national originality, and national mind and genius, ennoble modern countries, while not despising the useful Roman foundation of art established in each. If the Italian fine-art school rose first, it should be remembered that Italy was the sole place of deposit for the sculptures and paintings brought as spoils from Greece, some of which paintings remained till the time of Pliny, and probably long after.

THE BRISTOL AND CLIFTON JUNIOR ARCHITECTS' SOCIETY.

The first half-yearly meeting was held at Rupert-chambers, Rupert-street. Mr. John C. Monorieff, vice-president, presided. Messrs. George E. Ford and Wm. E. Hill, hon. secs., presented reports, from which we take the following:—The society was first instituted on the 8th of February of the present year, and the following gentlemen composed the preliminary committee:—Messrs. Cridland, Fawn, Fudge, and McPherson, with Messrs. G. E. Ford and W. E. Hill as honorary secretaries. The first meeting of the committee was held at 31, Clare-street, by the kind permission of Mr. W. L. Bernard, and Mr. C. F. Hansom, F.R.I.B.A., was chosen president, and Messrs. W. L. Bernard and J. C. Moncrieff vice-presidents. The thanks of the members and committee are due to these gentlemen for so readily consenting to fill these offices. The secretaries deemed it advisable to obtain a list of patrons. The programme of the society contained in its list of patrons no fewer than fourteen noblemen and gentlemen. This list, however, we have now increased to 32, which comprises six peers of the realm and other noblemen, members of Parliament, &c. Lectures have been given during the session by Mr. Henry Masters, on "Sanitation"; by Mr. J. C. Moncrieff, on "Art"; and by Mr. W. E. Hill, on "Apprenticeship." We have pleasure in noting that the society has already assisted in promoting two good objects, viz.,—the new St. Saviour's Church and the Bristol Benevolent Institution, for at the bazaars in aid of these objects the society exhibited large collections of drawings. It is greatly to be desired that the connexion already formed between the Bristol Fine Arts Academy and our society should increase, and that our members should look on the Academy not only as a place to meet in, but as a place to acquire learning and knowledge; for the advantages to be derived from the study which the Academy affords are not to be underrated. We also trust that our society may in time become linked to the Academy, as was the old society, and that the privileges enjoyed by the old society may now be enjoyed, in some parts at least, by our society.

The chairman, in moving the adoption of the report, congratulated the members on its successful bearing, and trusted that the number of members—at present fifty-two—would by the next report be at least doubled. He enumerated the advantages to be gained by the society being connected more closely with the Academy of Arts, and trusted that the members of the society would avail themselves of the opportunities of study afforded by that institution and the University College.

It was decided, with a view of further increasing the advantages of the society, and to further promote the study of architecture in Bristol, that a prize competition should be at once started, to be open to the architectural students and others connected with art in Bristol, all competitors to be non-members of the society.

A vote of thanks to the chairman, proposed by Mr. W. E. Hill, seconded by Mr. Geo. E. Ford, and unanimously carried, terminated the proceedings.

LINCOLN'S INN CHAPEL.

Some of our readers will doubtless be glad to know what is really about to be done here.

The chapel is to be lengthened one bay, and the present west window is to be taken out and re-erected in the new west wall; the stained glass in it is also to be preserved and replaced in the window. The two new side windows are to be exact copies of the present ones, the roof also. The west gallery and organ have been taken down, and are to be re-erected against the new west wall. The new seats are to be similar to the old ones. The crypt below will have also a bay added to it corresponding to the present ones, and similarly groined, and there will be a new west staircase. Every care, we are assured, is taken to preserve all interesting points. Mr. S. Salter is the architect engaged on the work

THE FISH MARKET QUESTION.

The inadequacy of Billingsgate Market and its approaches to the business of the fish trade of London and its surrounding districts seems to be generally admitted, and various suggestions have been and are being made on the subject. Among the numerous proposals that have been made is that the new Central Fruit and Vegetable Market in Farringdon-road, now approaching completion, should be experimentally used as a fish-market, its situation being convenient for the reception of railway-borne fish, as the basement is laid with rails in direct communication with the Great Northern, London, Chatham, and Dover, South Eastern, and other railways, so that the truck-loads of fish could be brought direct to the market. In the event of the experiment succeeding, it is suggested that the new market should be permanently devoted to the fish trade, as a supplement to Billingsgate, which latter market would then be chiefly devoted to the sale of water-borne fish. The needs of the fruit, flower, and vegetable trades in the City could, it is urged by those who make this suggestion, be suitably met by the erection of a new market on the site of the existing Farringdon Market.

Another suggestion, which appears to be worth consideration, although the site proposed is not in the City, is to establish a large fish-market at Bankside, Southwark, — between Southwark and Blackfriars Bridges. This site would seem to be capable of combining, to a very great extent, facilities for the reception and disposal of both water-borne and railway-borne fish, and the position is certainly not less central than Billingsgate. This proposal has been brought before the St. Saviour's District Board of Works by Mr. J. Leeuw, who says:—"We have at Bankside, Southwark, an area of about 365,000 superficial feet, which can, and at proportionate small expense, be extended. The area I propose is from Emerson-street corner, Bankside, to the corner of Love-lane, which is about 270 yards; thence through Love-lane to the corner of Sumner-street, 175 yards; thence to the corner of Emerson-street, down Little Park-street, 300 yards; and thence to Bankside, 120 yards. This area has a splendid foreshore and quay, and could be had at a proportionate small expense compared with the cost which for other places on the City side would have to be paid. On the back of Great Guildford-street, now called Sumner-street, is a large area, consisting of small tenements, which are now occupied by poor people in a more or less unenviable state, and which could be purchased very cheap. Converting this into a fish-market would even be a great improvement to London, the place being exactly opposite St. Paul's Cathedral. The area I propose is next door to the Chatham and Dover Railway, Blackfriars-road, which is not only in communication with the south coast, but also with the Great Northern and Great Eastern Railways, and nearly all the railways from the north and east, by which, according to admitted statistics, the greatest quantity of fish is sent up to London." The site above indicated could, Mr. Leeuw urges, be extended eastward as far as the west side of Southwark Bridge-road, at comparatively small expense, by the removal of three blocks of buildings bounded on the south by Sumner-street, on the north by the river, and on the west by Emerson-street and Park-street. Unless the proposed market area were thus extended eastward from the first, it does not appear to us that the street approaches would be adequate; and even then it would, it seems to us, be necessary to widen Great Guildford-street and one or two other streets leading from the suggested site to Southwark-street.

Queenhithe is suggested by Mr. Frederick Todd as a site possessing the following, among other advantages:—(1) That it affords an area four times that of Billingsgate Market. (2) A position more central, standing isolated, and having approaches on all sides. (3) Approaches commensurate with the increased size of the market. (4) Proximity alike to the river and to the district and extension railways; by which latter would be afforded constant and rapid means of communication to all districts lying north of the river. Mr. Todd urges that by the selection of the Queenhithe site, there could be erected two spacious markets, an upper and a lower one, both well lighted and ventilated, each about 535 ft. in length by 193 ft. in width, (the upper market, on a level with Queen Victoria-street, for general and retail business, the lower market, on a level with Upper Thames-street, for wholesale business), and giving extensive ranges of stall for the exhibition and sale of fish, amounting collectively to nearly a mile in length. He estimates the cost of the suggested market, including the land and all interests, at 840,600*l*. We are not so certain as Mr. Todd seems to be that the realisation of this scheme would not transfer to Upper Thames-street the condition of things which, as regards congested street traffic, now prevails in Lower Thames-street. Nevertheless the proposal, of which we have only given some of the details, is worthy of the consideration which it will doubtless receive in the City.

The site of St. Katharine's Docks and that of the Custom House have also been mentioned as desirable situations for a new fish-market. Of the former site, which would be exceedingly costly, it must be said that if chosen as the *locale* of a central market for the whole metropolis it is likely to prove too far out of the centre of London for the convenience of the trade (and this objection applies with increased force to suggested sites in St. George's-in-the-East and Shadwell, however well adapted they may be for local markets); while of the site of the Custom House, even supposing that the Government would or could dispose of it, the question of improved approaches and standing-room for railway vans, fishmongers' carts, and costermongers' barrows would still have to be considered.

As to the Blackfriars site, which seems to have found favour with a section of the Corporation, we cannot see that it would be suitable. The site proposed is on the north side of the Thames, a little to the eastward of Blackfriars Bridge. Have the proposers of this site forgotten that the London, Chatham, and Dover Railway obtained powers, in the last session of Parliament, to erect a new City terminus at this very point? Room for the terminus or for the market there may be, but there certainly would not be room for both (assuming that the proposers of this site do not intend to interfere with the large and costly block of buildings known as the City Flour Mills), unless it is in contemplation to utilise the space beneath the terminus as a market.

We see that at the meeting of the Metropolitan Board of Works, on the 30th ult., a letter was received from Mr. P. E. Masey, suggesting that the site of Millbank Prison should be appropriated to market purposes. This suggestion, and others on the same subject, were referred to the Works Committee for consideration.

ROSEWOOD.

Rosewood was once, even if it be not now, a fashionable wood. It was used for costly furniture and pianofortes. There is no information respecting its first employment; but it appears certain that it became known soon after the discovery of South America. Old writers speak of rosewood cabinets and other furniture made of it. The wood is met with only in South America. The French give it the name of "palisandre"; by the Germans it is sometimes called "Palissanderholz." What they term "bois de rose" or "Rosenholz" is, in reality, an African wood, and red with yellow streaks. It seldom attains a diameter of more than 8 in., and is cut into veneers to be used as a bordering in inlaid work or for floors. But the best quality of rose or palisandre wood is found in Brazil. All the finest descriptions of this wood are exported from Rio de Janeiro. Larger quantities of inferior kinds are sent out from Bahia. The latter sort, however, is only worked for cheaper articles, the fibre having a dark red colour and but few beautiful veins. Honduras also exports a description of heavy dark-coloured rosewood, which is mostly made into drumsticks and walking-sticks. The Rio de Janeiro wood grows to a good size, and has beautiful veins. The best is chosen for veneers; but the ordinary blocks with straight fibre look very rough and knotty. Rosewood is at present sold by weight; formerly it was disposed of by trunks. It contains a very stringent oil, which must be extracted by steam or else by long exposure to the air, before the wood can be glued. It has also a powerful smell, and people who work it seem to be penetrated with it. Nothing can remove it, and the worker in it may be easily distinguished from such as work in other woods; the dust rising from the wood when it is being rubbed with sand-paper is not poisonous, but it imparts to the face of the workman a peculiar, ghastly, expression. Rosewood is, if properly worked, the most durable description of wood, and may even after a hundred years' use be polished again so well that it looks like new. It is extremely hard and strong, and becomes harder with age.

AN ELASTIC LACQUER.

A patent has been taken out in Germany for a new description of elastic and flexible lacquer, which will not peel off, and which is suitable for the coating of carriage-cloths, plans, and other articles to be folded up, as well as for wood and iron work, walls, &c., but which may also be employed as an isolating layer for damp rooms, as a means against dry-rot, and in rendering stuffs waterproof. To produce the lacquer, 50 kilogrammes of linseed oil varnish are heated up to boiling-point. In another vessel about 15 kilogrammes of lime are slaked in 20 kilogrammes of water. As soon as the lime boils, about 50 kilogrammes of hot melted raw caoutchouc are added to the lime water, and the whole is stirred until it has become thoroughly mixed. This composition is poured into the boiling varnish, the whole being stirred all the time. Further stirring takes place until a homogeneous mass is formed, which is afterwards strained or filtered, and left to cool. After cooling, the lacquer has a pap-like consistency. To apply the lacquer, it is diluted with the desired quantity of varnish, and put on with brushes either in a warm or cold state. But it is said to be better to apply it warm, as then no varnish is required for diluting it. In rendering linen waterproof, the lacquer may be put on by means of brushes or rollers. After treatment, the linen or other stuffs, paper, &c., are hung up to dry. Stuffs are perfectly dry and ready for use in two days. The product is stated to be lustrous, elastic, not sticky, and perfectly waterproof.

NEW BANK BUILDINGS AT BRIXTON.

On a recently-cleared site at the corner of Brixton-road and Canterbury-road, a block of new buildings is at present in course of erection for the London and County Banking Company. The building has a frontage to Brixton-road, 24 ft. in length, with a return frontage of 55 ft. long, to Canterbury-road, the two elevations being 40 ft. in height, and uniform in architectural design and execution. The ground-floor portion of the two frontages, up to the first-floor windows, is in Portland stone, the elevation being faced with pilasters surmounted by carved capitals. The windows are arched and recessed. The upper portion of the building, consisting of two floors, is faced with red brick, with a free introduction of Portland stone for dressings and ornamentation. The entrance to the premises is in the Brixton-road frontage, which leads into the banking-room, an apartment 22 ft. by 28 ft. Immediately behind the banking-room is the manager's room, together with clerks' room and a waiting-room. A deep basement contains the strong room, the walls of which are built in brick and iron, with cement, the room being fireproof. The two upper floors form the manager's residence, the first floor containing a spacious drawing-room overlooking the Brixton-road, with dining-room, library, and other apartments in the rear. The second floor contains several bedrooms. There is a separate entrance to the manager's residence at the rear of the Canterbury-road frontage.

The architect of the building, as well as of some shops adjoining it, is Mr. C. Val. Hunter, of Wardrobe Chambers, Doctors'-commons. The builders of the bank are Messrs. Hill & Higgs. Mr. Greenwood is foreman of the works. The adjoining shops are being erected by Mr. J. Taylor.

Royal Exchange Roof.—We have seen the drawing now on view in the Merchants' Area, and quite agree with our contemparary, the *Builder*, on the subject of its most unsuitable and objectionable character. We think that it is only necessary, as it is certainly only just, that Mr. Sang's drawing, which obtained the prize among so many others when public competition was invited, should be exbibited, to disperse all doubts as to which or what design should be carried out.—*City Press.*

ECCLESIASTICAL ART EXHIBITION AT NEWCASTLE.

On Monday evening the Ecclesiastical Art Exhibition in connexion with the Church Congress was opened at the Northumberland Rooms, Pilgrim-street, Newcastle. Close to the entrance-door Messrs. Jones & Willis display a large collection of church furniture and articles of decoration. Messrs. J. Wippell & Co., of Exeter, show brass altar vases and church-fittings such as gaseliers, lamp and gas standards, &c. In the gallery at the west of the building an entire section is set apart for the exhibits of Mr. G. J. Baguley, artist in stained glass, Carliol-street, Newcastle. In one of the side rooms of the gallery which encircles the hall are the exhibits of Messrs. Cox, Sons, Buckley, & Co., London. Adjoining is the stand of Messrs. G. M. Hammer & Son, who exhibit school and church furniture. Messrs. Doulton & Co., of Lambeth, are exhibitors of several terra-cotta reliefs intended for reredoses, &c, illustrating incidents in Scripture history, and modelled by Mr. George Tinworth. Messrs. Lavers, Barraud, & Westlake, of London, exhibit a two-light window, containing figures of SS. Ambrose, Athanasius, George, and Katherine, together with three designs for decoration.

The Loan Collection contains some interesting items, including a collection lent by Mr. Wm. Bragge, F.S.A., of Birmingham, of 124 Russo-Greek "Icons," or religious pictures, chiefly in brass, many enamelled; some painted and mounted in silver, and silver gilt; twenty-four are crucifixes, sixty-four are single plaques; the remainder are diptychs, triptychs, &c. The smaller icons are in very general use amongst the Russian peasantry, and also amongst the wealthier classes, those worn by the latter being, however, of a much more costly character—some are even of gold. When a peasant is about to send his son to service in the army, he often takes from his neck the icon that he and his forefathers have worn, and places it with his benediction on the young soldier's breast. To the soldier himself the icon becomes a memento of his country, of his family, and of his religion, —of his country because it usually bears the effigy of some Russian saint, very frequently the patron, St. Nicholas; of his family, for this icon may have been an heirloom; of his religion, for when about to offer his prayers he opens his triptych or diptych and kneels before it as a portable altar. He carries it, suspended to his neck, through the vicissitudes of a campaign; and when, his labours ended, he returns to his native parish, he often lays his cherished possession upon the iconostasis of his village church, as a votive offering to commemorate his preservation. The subjects most frequently represented are events in the life of the Redeemer or the history of the Virgin Mary, Russian saints with their appropriate symbols, and copies of certain local pictures of the saints, some of which are highly venerated. They usually consist of the name of the saints, contracted in the most arbitrary manner, or of some short sentence descriptive of a portion of the picture, as "The Son of God," "The Angels of the Lord," and the like; though sometimes, as in the case of the crucifix and of the religious medals, the inscription is a text or a prayer. The costumes of some of the figures exhibit, in an interesting manner, the peculiarities of Greek ecclesiastical vestments.

Mr. Henry E. Franks exhibits an interesting collection of rubbings of monumental brasses. Mr. C. Hodgson Fowler, Mr. B. Edmund Ferrey, and Mr. James Hicks are among other contributors to the loan collection.

BIRMINGHAM.

Extensive Street and other Improvements.—On the 23rd ult., Mr. J. Thornhill Harrison, C.E., one of the inspectors of the Local Government Board, held an inquiry at the Council House, Birmingham, relative to the application of the Corporation to borrow 127,700*l.* for works of sewerage and street improvements, for providing public baths, and for market and fire-brigade purposes. The Town Clerk explained the various purposes for which the amount of loan was asked and the sums required for each item in the application. The first were for 11,025*l.* for the purchase of the site for the central fire-brigade station, and 10,000*l.* for the erection of the station. The amount of the builder's contract was 9,355*l.*, and the architect's commission, salary for clerk of works, &c., were estimated at 645*l.* They would also require for the construction of a market-house and other conveniences on the site of the present Smithfield Market, for the purposes of a vegetable market, 21,000*l.*; for the purchase of the leasehold interest in the Woolpack Hotel, for the widening of St. Martin's-lane and Jamaica-row, 7,400*l.*; for the erection of shops, buildings, and hotel in St. Martin's-lane and Jamaica-row, and other works in connexion with the market in consequence of the purchase of the Woolpack, 14,000*l.*; and for completing the purchase, from the governors of the Grammar School, of certain freehold land in Spiceal-street for the enlargement of the fish-market, 8,400*l.* Dealing next with the 22,000*l.* required for the erection of public baths in Monument-road, the Town Clerk explained that such provision in that quarter would meet a great want, and would complete the bath accommodation in the four districts into which the borough might be divided for that purpose, viz., north, south, east, and west; 30,000*l.* were also required for the Cole Valley sewer from Stratford-road to Tyburn, and the branch sewer from the same to the outfall sewer in Muntz-street; 1,000*l.* for effecting improvements in Snow-hill, Henrietta-street, Hampton-street, and Constitution-hill; 2,500*l.* for the purchase of the leasehold interest in Nos. 1 and 2, Moor-street, and 15 and 16, Bull-ring, for the purpose of widening and improving these streets; and 300*l.* for widening and improving Balsall Heath-road bridge and contributing one moiety of the cost. The amount of 75*l.* set down for legal expenses made up the amount of loans required to the total,—127,700*l.* Alderman Avery explained, with reference to the sewerage scheme, that the area of Birmingham was 8,400 acres, of which 956 acres were in the Deritend and Bordesley district, and naturally drained towards the Cole. Up to the present no proper system of sewerage or treatment had been adopted, because no resources had been within the reach of the authorities. In Deritend and Bordesley there were at present twenty-four miles of streets and twelve miles of sewers. The population was only 7,500, but was very much on the increase, and the time had arrived when the urgency of the question demanded attention. It had been considered much more convenient for one authority to undertake the whole of the work, charging a certain sum to each constituent authority, according to the extent which they used the sewer. It would be a very complete and effective scheme, and would provide ample accommodation for 100,000 persons, whereas 16,600 was at present the actual population of the area. The Borough Surveyor said the estimated cost, according to the route planned, would be 28,272*l.*, exclusive of compensation, or 29,560*l.* by the alternative route, by which the expense of 700 yards of public highway would be saved.

The New Central Fire Brigade Station.—On the 30th ult. the memorial-stone of this building, now in course of erection for the municipality, was laid by Alderman Deykin. The site is in the Upper Priory, upon the line of Corporation-street, and appears to be one of the most suitable that could have been selected. Over 20,000*l.* will be expended in providing the premises, 11,025*l.* being given, as above mentioned, for the purchase of the site, and 10,000*l.* for the erection of the buildings. The arrangements are intended to be the most complete in the kingdom. There will be accommodation in the engine-house,—the internal measurement of which is 95 ft. by 17 ft.,—for six engines, and the stabling will have room for a similar number of horses. There will be workshops and residences for the superintendent, the assistant superintendent, and the firemen, with their families, while a drill-ground, 150 ft. in length and with an average width of 40 ft., is included in the plans. There will also be a large washhouse, with a cover for washing the hose, with a lofty chamber for subsequently drying it. Over the engine-house will be a spacious store-room, a loft, and a reserve room for the firemen when not on active duty. Two bath-rooms will be so placed as to be available for the use of families as well as of the firemen, without their encroaching upon the working departments. The contract for the erection of the fire-station has been secured by Mr. W. T. Bennett, and the work is being proceeded with with all possible expedition. Messrs. Martin & Chamberlain are the architects, and Mr. Clapp is the clerk of the works.

The New Free Library.—The nineteenth annual report of the Birmingham Free Library Committee has just been issued. In it the committee say that the reconstruction of the library buildings in Ratcliff-place is now making satisfactory progress, although in the early part of the year difficulties occurred which caused much delay. The architects are of opinion that both the Lending and Reference Libraries will be ready, if not by the end of the present year, certainly early in the year 1882. With reference to the art gallery, the report details the course of events leading to the commencement of the new art gallery, following on Mr. Tangye's munificent offer.

A RECLAMATION.

MR. BEER'S MAUSOLEUM.

Monsieur,—Une circonstance fortuite me fait connaître tardivement une erreur qu'il est de mon devoir de vous signaler. Cette erreur remonte au 18 *Mai*, 1878, mais, pour n'avoir pas été relevée plus tôt, elle n'en est pas moins réelle, et j'espère ainsi que vous m'accorderez de la rectifier.

J'ai en effet étudié, à la demande de mon ami, feu M. Jules Beer, les projets du monument exécuté au cimetière de Highgate; mes projets ayant été approuvés, je les ai completés par un modèle au $\frac{1}{4}^{\text{eme}}$ de l'exécution, permettant de connaître, dans toutes ses parties, l'appareil de la pierre de la construction, et à ce modèle j'ai joint, outre les dessins au $\frac{1}{8}^{\text{eme}}$, tous les détails, grandeur, tant des profils que des ornements. Vous comprendrez ainsi ma surprise, quand, feuilletant votre estimable journal, j'y ai trouvé, au volume xxxvi., No. 1,841, du 18 Mai, 1878, pages 512 et 513, une perspective du monument de la famille Beer, et une notice en attribuant la composition et les dessins à Mr. John O. Scott, architecte.

C'est là une erreur qu'il faut attribuer à ce que l'exécution de mon travail, s'est, il est vrai, faite sous la direction de Mr. Scott, auquel la publication de votre journal aura échappé et qui tiendra sûrement autant que moi à réparer une omission involontaire.

Je n'hésite donc pas à vous la signaler, persuadé, que vous voudrez donner satisfaction à une réclamation dont le bien fondé ne saurait vous échapper.

Je vous remercie d'avance et vous prie d'agréer, monsieur, les expressions de ma parfaite considération. W. Bouwens, v. d. B.

Paris, Sept. 6.

*** On mentioning this communication to Mr. J. O. Scott, that gentleman writes us:—

It is quite true that the first design for Mr. Beer's mausoleum was made by M. Bouwens, of Paris, and had I been at home when the view appeared in the *Builder* I should certainly have taken care to state the fact. I did not know that any view had been published. The circumstances were as follow:—Mr. Beer procured a complete design, with full-sized drawings and a model, from M. Bouwens. He inquired of me through a mutual friend whether I should have any objection to superintend the erection of the mausoleum, and after some discussion it was agreed that I should do so, but should be at full liberty to make any alterations in the design which I thought desirable. I then set to work and remodelled the design, altering it very considerably both in its proportions and in its detail, and so it has been built. It is a joint work, as the leading ideas of the first design have been kept to, while it has been much altered in all other respects.

I shall be very glad if you will communicate this to M. Bouwens, with my best compliments, and I regret that such an oversight should have been made. If I remember rightly, M. Bouwens quite agreed to my dealing with the design as I might think best; but I am not clear about this, as it was only told me by Mr. Beer by word of mouth. J. Oldrid Scott.

SURVEYORSHIP ITEMS.

Lewisham.—At a meeting of the Board of Works for the Lewisham District, held on Wednesday, the 28th of September, Mr. E. van Putten was appointed assistant surveyor to the Board. There were between fifty and sixty applicants for the position. Mr. van Putten was articled for three years to Mr. C. W. Whitaker, of Great George-street, Westminster. Since then he has been engaged in the superintendence of various public works.

PATENT RECORD.*

APPLICATIONS FOR LETTERS PATENT

3,993. W. Wyman, Gloucester. Heating water for baths, &c. Sept. 16, 1881.

4,001. J. Shanks, Barrhead. Baths, sinks, &c. Sept. 16, 1881.

4,010. J. Imray, Southampton-buildings. Cooking-stove. (Com. by La Société des Spécialités Mécaniques réunies, Paris.) Sept. 17, 1881.

4,020. G. West, New Lenton. Smoke-consuming apparatus. Sept. 19, 1881.

4,033. W. Wright, Plymouth. Flush-cisterns for water-closets, &c. Sept. 19, 1881.

4,042. S. Clark, Islington. Gas and oil stoves for heating and lighting. Sept. 19, 1881.

4,050. A. Martin, Woolwich. Springs for doors, &c. Sept. 20, 1881.

4,054. E. De Pass, Fleet-street. Concrete materials for blocks for paving and building. (Com. by W. Hunt, New York, U.S.A.) Sept. 20, 1881.

4,065. W. White, Abergavenny. Building damp-proof walls, &c. Sept. 21, 1881.

4,077. C. H. Pennell, New Quay. Holding and controlling blind and other cords. Sept. 21, 1881.

4,083. W. Richards, Norwood. Apparatus for measuring water. Sept. 22, 1881.

4,085. C. H. Murray, Southwark. Apparatus for shaping and moulding clay for bricks, tiles, &c. Sept. 22, 1881.

4,090. W. Saunders, Stepney. Cleansing floors, &c. Sept. 22, 1881.

NOTICES TO PROCEED

have been given by the following applicants on the dates named.

September 20, 1881.

2,131. F. H. F. Engel, Hamburg. Petroleum or hydro-carbon cooking and heating stoves. (Com. by H. Kock, Hamburg.) May 16, 1881.

2,132. J. Hurst, Brighton. Portable crane for builders, &c. May 16, 1881.

2,149. T. F. Shillington, Belfast. Fireplaces or stoves. May 17, 1881.

2,160. E. S. Harvey, Tottenham, and J. Brodie, Bloomsbury. Attaching knobs to door, lock, and other spindles. May 18, 1881.

2,171. R. Stone, King William-street. Burning lime, cement, bricks, &c. May 18, 1881.

2,174. J. Walker, Leeds. Manufacture of bricks, tiles, &c. May 18, 1881.

3,318. W. H. Poole, Briston. Furnaces. July 30, 1881.

September 23, 1881.

2,222. A. McMillan, Thornliebank. Mode of applying springs to doors. May 21, 1881.

2,229. S. H. Ogden, Manchester. Firegrate screens. May 21, 1881.

2,254. H. Wedekind, Fenchurch-street. Brick-pressing machines. (Com. by O. Hoffmann and H. Dneberg, Berlin.) May 24, 1881.

2,759. S. L. Coales, Newport Pagnell. Door latches. June 24, 1881.

3,037. J. Gooddy, Wombwell. Securing the joints of earthenware and other piping. July 11, 1881.

ABRIDGMENTS OF SPECIFICATIONS

Published during the Week ending Sept. 24, 1881.

4,604. G. E. Waring, jun., Newport, U.S.A. Sewers, &c.

The main sewer-pipe gradually diminishes in size, and is provided with branches, on the ends of which automatic flush-tanks are situated, and it has connecting sewers with the houses which form open flues to the tops of the houses. Subsoil drains are laid in the same trench as the sewer-pipes to carry off the storm-water. The pipes are supported by broad piles driven into the ground. The joints are made by wrapping strips of paper round the ends of the pipes. Nov. 9, 1880. Price 10d.

440. T. Jackson, Edinburgh. Apparatus for supplying, heating, and circulating water for domestic purposes.

A high-pressure boiler is placed in the kitchen range, which is connected with the supply-cistern at the top of the house, and in which the water is heated and carried to the service-cisterns on each floor. To prevent accidents to the boiler, when the supply-cistern is empty another series of pipes is led from each of the service-cisterns back to the boiler, which can be opened in case of need. Feb. 2, 1881. Price 6d.

448. E. A. Rippingille and J. D. Rippingille, Aston-juxta-Birmingham. Lamps and lamp-stoves.

The height of the oil in the tank is indicated by a prism of glass mounted in the top of the tank. When one chimney only is employed in an oven, as described in the specification of Patent No. 680 of 1880, a channel is formed on one side, which is in communication with the top of the chimney, thereby heating the lower part of the oven. The stoves may be constructed with more burners and chimneys intermediate of the side-burners, and forming an oven on each side. Feb. 2, 1881. Price 6d.

498. E. Edmunds, Fleet-street. Kilns.

The kiln is a gallery or bricked chamber, under which atmospheric air is allowed to circulate. The gallery contains a certain number of trucks, with bottoms and sides of refractory material in which the cement or bricks, &c., are placed. The bottoms of the bricks form the sole. In the middle of the length of the gallery are placed underneath four recuperators of heat in pairs, two for air and two for gas. Twelve flues are placed above them, terminating in mouths on a level with the sole. The hot air and gases leaving these mouths ignite, burn the materials in the trucks, and are then sucked in to the mouths of the other set of recuperators, and thence pass to the draught chimney. A gazogene on the Siemens system is placed at the side and the back of the kiln. (Com. by C. Amand, Tournay, Belgium.) Feb. 5, 1881. Price 8d.

600. J. D. Sprague, Norwood. Cords for suspending pictures, &c.

The strands of wire or hemp, flax, &c., are twisted to form a line or cord, but have loops or eyes at regular intervals to receive the hook of the picture, &c. Feb. 11, 1881. Price 4d.

610. P. Stuart, Edinburgh. Manufacture of Paving, Floors, &c.

A layer of small stone is first laid. On this is placed a layer of concrete, composed of pulverised oxide of iron and crushed stone, &c., mixed with cement and water. For outside paving, grooves are made in the concrete, in which iron rods are laid at right angles to each other. On this surface a composition of granite, with pulverised oxide of iron, hæmatite iron ore, and cement is spread and levelled. This composite pavement is laid in alternate squares, the layer of concrete in each alternate square projecting beyond the upper layer of granolithic composition. Feb. 12, 1881. Price 6d.

705. F. W. Fletcher, Westminster. Metal substitute for putty.

A strip of thin, hard metal, curved in its width, is fixed to the glazing bar in such a position that one edge of its convex surface shall press against the surface of the glass. (*Pro. Pro.*) Feb. 18, 1881. Price 2d.

706. J. H. Jack, Edinburgh. Close and open cooking ranges.

This relates to the construction of a flue-doorway in the vertical back or cove-plate, leading right into the central back-flue over the hot plate. The upper outer edge of this flue has a flat door. (*Pro. Pro.*) Feb. 18, 1881. Price 2d.

707. R. Brierley, Preston. Securing window-blinds to rollers.

A groove is formed lengthwise in the roller to receive the end of the window blind, which is secured therein by a strip of wood or metal. (*Pro. Pro.*) Feb. 18, 1881. Price 2d.

727. S. H. Adams, Leeds. Apparatus for flushing and ventilating drains, &c.

A syphon has an internal smaller syphon, the discharge through which withdraws the air from the larger syphon, and brings it quickly into action. A small hole is made in the inlet leg of the large syphon above the point at which the liquid is drawn off, so that when the water in the tank falls below this hole, air is admitted and the syphon is put out of action. For ventilating drains, the gas from the drain is made to pass through a chamber, through which also a current of fresh air is continually passing, which dilutes the gas and renders it less injurious. Feb. 19, 1881. Price 6d.

1,476. R. H. Brandon, Paris. Producing designs and ornamentation upon artificial ivory.

The designs, &c., are produced by compression in heated dies or moulds, in connexion with which an ink or sizing is used which carries a colour. The pressure is applied long enough to cause an absorption of the ink or colour, and the heat is applied afterwards. (Com. by J. S. Hyatt, U.S.A.) April 6, 1881. Price 2d.

* Compiled by Hart & Co., Patent Agents, 28, New Bridge-street, E.C.

COMPETITIONS.

Fulham Infirmary.—At the meeting of the Board last week, a letter was read from the President of the Institute of Architects, naming three architects for the Board to select one to advise them on the merits of the twenty-six sets of plans for the proposed new infirmary which had been received. The fee to be paid was 100 guineas. The architects named were Mr. H. Currey, Mr. P. C. Hardwick, and Mr. E. l'Anson. Ultimately Mr. Currey was selected.

Museum, Dublin.—Sir, I sent a note a few days ago asking for an extension of time in connexion with this competition, and in reply the secretary wrote, "It is not considered necessary to extend the time, as the number of applications for the conditions for the competition has been very large, and there have been but two applications for the extension of time."

I have now to suggest that those among the intending competitors who find the time too short should at once write asking an extension of at least a month. It is quite evident that no architect whose time is otherwise much occupied can do anything like justice to this competition within the time allowed at present.

AN ARCHITECT.

Cleopatra's Needle. — The second bronze cast of the sphinxes, executed by Messrs. Young & Co., is ready for erection, and only awaits the necessary preparations for its removal to the base of the needle.

ON THE USE OF THE WORD "NATURE" IN REFERENCE TO ART.

SIR,—Your own desire, as that of your correspondents, is, doubtless, to elicit truth for the advantage of the future. I need not, therefore, apologise for addressing you again on the subject of the use of the word *nature* in reference to art. "In the multitude of councillors there is wisdom"; albeit, in the discussion in council there may appear to be some confusion.

In all that I write upon art I have a mathematical calculus ever present to my view and to guide me, though I may avoid mathematical expressions in my discourse. Now, the very fact that there is wisdom in the multitude of councillors bears upon an affirmation of mine to which you take exception, for it depends upon the law of probability that, in the aggregate, men will err as often on the one side as on the other of the mean of truth, and so, from the average of opinion, common sense is attained. The neutralisation of opposite views ultimately causes men to tread in the middle course. This law of probability obtains in forming a just estimate of nature's intent in all kinds of natural phenomena; by its means we may arrive at a just conception of the good and the beautiful. I, therefore, venture to repeat with confidence what I stated in my letter of the 3rd ult.,—that the general tendency of nature is to the middle course between opposite extremes. If this were not the general tendency of nature, then nature's general tendency would inevitably be either to the extreme of excess or to the extreme of defect. The logician will understand that this position is incontrovertible. Some persons, indeed, might possibly argue that there is no general tendency or direction in nature; that nature is a mere chaos of manifestations. This assumption would at once sweep away the idea of moral governance,—direction,—in nature. If this were true, it would, of course, be immaterial what course men should pursue either in conduct or in art.

But to affirm that the general tendency of nature is in a course between opposite extremes is to affirm that the general tendency of nature is towards the symmetrical or proportioned, *i.e.*, that its general tendency is a moral tendency, whereas if it were to either extreme of excess or of defect it would be immoral, just as we know it is in one section of nature, the human. In your leader of the 24th ult. you bear witness to the truth that nature recognises the force of the axiom *in medio tutissimus ibis*, in the following passage, "Anything like absolutely geometrical symmetry is, in fact, the exception in the forms of the vegetable kingdom, and in the animal kingdom even is only to be found in the main disposition not in the details. The hands are symmetrically disposed, but the hand itself is quite unsymmetrical." Just so, I should have said, if regularity had been substituted for "symmetry," and irregularity for "unsymmetrical," for the human form, which is regarded as the highest type of animate existence, is neither too regular nor too irregular; its highest beauty depends upon its being proportioned or balanced between extreme regularity and extreme irregularity.

It is a mistake to confound the symmetrical or proportioned with the geometrically regular; the regular geometrical figures are abstractions seldom or never realised, with mathematical exactness, in the concrete, and they are in all cases extreme forms. The symmetrical in its true sense means the proportioned, not the geometrically regular, and the proportioned in every species of phenomenon is that which lies between its extreme manifestations.

Notwithstanding it is a province of art to give to airy nothings a local habitation and a name, I would rather not for my own part, forcibly as you argue for it, admit the word "metaphysics" into the contention, partly because metaphysics appear to me to be wholly beside the question at issue, and partly because our friends the artists are "so absolute" that its use might frighten them from the discussion. The question is not now how we should denominate the various subdivisions of nature, but what meaning it would be most expedient to attach to the word "nature" to ensure greater unanimity in arguments upon the principles of taste. The prevailing notion amongst one section of artists and critics, which vitiates art discussion, is this,—that whatever is to be found in nature sanctions its use in art. If this were true, nature would sanction anything and everything in art; for nature, as defined by Professor

Huxley, is the all-including. He defines it thus: as "the sum of phenomena presented to experience; the totality of events, past, present, and to come." The word "nature" in this, its all-including sense, and as I would have every artist and critic accept it, brings us at once to our bearings in art discussion; for as anything and everything are to be found in nature, we are at once compelled to inquire whence the sanction for the acceptance of certain conditions, and the rejection of certain other conditions, in art? We reply that this is to be found either in their appositeness or in their inappositeness to correct judgment.

Art treatment, therefore, broadly divides into the imitation of the concrete,—realism; and the presentment of the abstract,—idealism. The first is the primitive, easier, and lower aim of art, because it is merely imitative; nature may be taken as it comes, it does not involve rational choice. The second is the later, more difficult, and higher aim, because it involves culture, considerable study, a knowledge of principles, and rational choice; nay, I believe I may even say, moral choice. Moreover, the definition of the word "nature" recommended for adoption shows us that the ideal is nature as well as the real. To the thinker it is the better nature of the two.

Mr. Colling thinks, in common with many other artists, that there is some position outside and apart from nature, from which it is a virtue to study nature. He and they cannot grasp the simple fact that there is no such position, and that there is nothing but nature to be studied, if we study at all; that the very worst and the very best productions of either human or external nature are nature, and equally the effects of natural laws, either special or general.

Mr. Colling is right, however, when he states that all ornament must have a geometrical basis. It cannot have any other. Whatever can be measured and delineated is geometrical. But if he means by this that all forms of growth exhibit a tendency to the regular geometrical figures in their arrangements, he is wrong. The most eccentric form is as geometrical as the most regular. Japanese ornament is as geometrical as the Greek, but it is not so symmetrical, and it is also possible for ornament to be more geometrically regular and yet less symmetrical than the Greek. The three terms of the scale of geometrical differentiation are the following:—

Extremely irregular configuration.	Symmetrical configuration.	Extremely regular configuration.

And the general principle which should sanction the leaning to either the one or to the other of these characteristics is that of adaptation to purpose, and the sanctity of the purpose is measured by the ratio of its goodness. But I fear I shall not yet be understood.

W. Cave Thomas.

VERGERS AND CATHEDRALS.

Sir,—The letters of "F.S.A." and "C. T. H." which have appeared in your journal are well timed; and as the subject has been so ably opened, it is to be sincerely hoped that you will use your powerful influence in mitigating a few of the hindrances which forbid (to the interested visitor) the full enjoyment of most of our cathedral churches.

"C. T. H.," as your readers have doubtless seen, refers to Salisbury. A visitor to the cathedral last week related to me almost word for word that delectable dissertation with which "C. T. H." entertained your readers in your journal of September 17th.

I visited the cathedral this week, and to my mute and joyful astonishment (without either tip or request) the verger volunteered to let me enjoy the mysteries of the choir in peace. I thought at the time that the correspondence in the *Builder* was bearing fruit.

The junior verger was equally obliging; for he in like manner, without demand from self, asked if I would care to remain in the chapter-house, an offer which was most gratefully accepted; so that, unlike "C. T. H." (to whom I am deeply indebted), I had an opportunity of feasting my eyes on a chapter-house second perhaps only to Westminster.

As regards York, my experiences last July were much the same as those of "F.S.A."

Having spent three weeks this summer at Lincoln I can add to "Mr. Harry Hems's" notice of the civility of the Exeter officials. I had ample opportunity of noticing the vergers of Lincoln Cathedral, Messrs. Logsdail and Barnett.

Mr. Logsdail has studied his subject well, and being always on the spot, has to a certain extent grasped the church as a whole. Whether to large or small parties, or to individuals, he seems most anxious to teach them as much as is possible while they are under his direction; of course, some appreciate this, others do not.

So that, at least in Lincoln, the visitor is not pestered by the up-and-down-hill shilling-seeking illiterate verger, so common, I am sorry to confess.

Yesterday I was in Wells, and the vergers here hand you a card upon which is printed a short description of the choir, &c., and the visitor is left to himself.

Let all deans and chapters of our cathedral churches follow the excellent example set them by their brethren of Wells.

If you, sir, through the powerful influence of your journal, could secure for students and others the privilege of making notes without leave, you will at least have the heartfelt and lifelong gratitude of one Student.

A WALK IN KENT.

Many are the places of historic and architectural interest that, not included in any regular tour, and unknown to excursion "there-and-back" travellers, remain in the almost untrodden freshness of their early beauty. The architect or the artist may plan numerous journeys which, in the compass of a few miles, are full of almost unknown beauty.

Such a journey was commenced one bright day not long since by a short ride to Edenbridge. The town has many old houses which, under modern lime-wash, show their massive timber construction, and some of the rooms are remarkably quaint with wrought oak beams and wooden ceilings. A narrow turning from the High-street to the church is suggestive of similar picturesque nooks in ancient towns and villages. Some Norman traces may be noticed in the church.

Through winding lanes, bordered by early primrose, Hever is soon reached. One of the smallest of the quiet villages of Kent, it seems as though three long eventful centuries have wrought but little change there. Two or three houses are newly built, otherwise, as the visitor ascends the hill where stands the village church and school, and inn, he sees the Hever where Sir Geoffrey Boleyn, mercer and Lord Mayor, retiring from city life, bought an estate; where his grandson, Sir Thomas, completed the castle thereon founded; and where gentle Anne walked and studied with her French "gouvernante" in the early, happy years of her short eventful life. The moated castle, the Boleyn chantry and tomb in the church, and the sign of "Henry VIII." on the village inn, recall the names of those whose presence gave fame to that country side.

A mile or more over the sand hills, through hop-gardens and flowery hedgerows and lanes, and the traveller arrives at Chiddingstone. That part of the village that adjoins the church is a rich specimen of timber construction, forming, with the church on one side, and the park at one end, a delightful picture. In the park, immediately behind the houses, are some prominent masses of rock, one of which, somewhat resembling a huge leaf, has been claimed to be the chiding stone where contentious parties met to have their differences decided. A solitary gateway, in the pseudo-Classic style, and bearing a sixteenth-century date, stands in the park near the rocks.

After walking rather more than a mile along the road, the traveller arrives at two lodges in the mock-fortress style; turning in a gateway adjoining the left-hand lodge, a beautiful avenue leads to the Classic "groves of Penshurst," nearing which the river crosses under the road and meanders among the meadows and pollards that skirt the village. Here the beauties of Kentish scenery are seen to advantage clustering round the ancient home of the Sydneys. Here the charms of nature, history, and archæology unite, and the traveller will be willingly mindful of Southey's words and

> "Tread
> As with a pilgrim's reverential thoughts
> The groves of Penshurst."

Under some quaint houses, where the beam of the lich-gate sets forth the bright words of inspiration,—"My flesh also shall rest in hope," is the principal entrance to the churchyard, a secluded resting-place shaded by the walls of Penshurst-place, and the church, partly rebuilt and modernised. Both should be seen. The former, the residence of Lord de L'Isle, has an almost unique example of fourteenth-century work in its hall, where the open timber roof, centre hearth, minstrel's gallery, and massive oak tables, and many other objects of interest, remain *in situ* to interest the visitor.

Another glimpse of the village, then along the park, where the famous oak still stands, two miles more through Kentish lanes, and then, as the shades of evening fall, to await the train at Penshurst Station. H.

"A VICTORY OVER SEWER GAS."

Sir,—I have read Sir Henry Cole's letter under the above heading, on pp. 419-20, and as it deals with what I have had considerable experience in for years back, I beg to say a few words upon the subject. Firstly, I would point out that the title seems to me to be a misnomer, as what Sir H. Cole and Mr. Mineard are really trying to fight is not "sewer" gas, but rather drain and soil-pipe gas; hence the word "sewage" would have been more correct. In my own practice with house-drainage, a "victory over sewer gas" is not worth while talking about, much less crowing over, as the sewer gas is easily shut off, practically speaking, by the insertion of one of my disconnecting ventilating-traps between the house and the sewer. The real fight, then, begins in protecting the inmates of the house from themselves, and it is really this fight which Sir H. Cole gives a description of on pp. 419-20, and on plates Nos. 1 and 2. Upon examining the plans, I find, as it seems to me, as a practical tradesman, that the writer is rather premature in claiming the "victory"; for his own account shows that there has really been no battle, but only a slight skirmish or two. So far as I can judge from the plans, when the real battle comes the upshot or result of the fight may be defeat and not victory, and that, too, notwithstanding the enormous forces employed.

The idea of using a heating force to bring the current of air *down* the soil-pipe and along the drain and then up a special shaft, is an old one. It will be found in the provisional specification of a patent by Mr. John Honeyman, F.R.I.B.A., dated 6th of February, 1868, No. 404, and so far as Mr. Mineard's "improvement," if any, is concerned, I hardly think the game worth the powder. We are told the expense for gas will be about 1s. per week, or 2*l.* 12s. a year; but, even with this expense, there is no real guarantee of safety, for it is well known that such an upcast shaft as is shown (it is only marked 3 in., too) will draw its supply of air from the openings nearest the heating-chamber, and so if the joints at, or stones over, the intercepting chamber, were not tight, no ventilation of the drain, even, might take place, far less of the soil-pipe as intended; then, as no traps are shown on the soil-pipe, what would protect the house? Further, to make this plan of Mr. Mineard's work, the gas must be kept burning day and night; while to make it work properly and against the action of the chimneys, I fear both Mr. Mineard's 3-in. pipe and his shilling's worth of gas a week are far too little.* Sir H. Cole's deductions from the experiments described by him are not warranted, I consider, and his recommendation of the plan so highly is far too premature, and, I may even add, dangerous. Too high laudation of newly-hatched plans has done a great deal of evil, and should be guarded against, and especially by scientific men of position; it is not every duckling that turns into a swan.

Permit me further to point out various other bad points in the plan of the drainage on No. 1 sheet.

1st. About 20 ft. of the drain from the servants' w.c. seems to be unventilated (if ventilated properly the ventilation downwards of the soil-pipe would be "waved").

2nd. Owing to the want of traps on the closets above, or if any leakage existed in the soil-pipe, then at the first chance foul air would come out, which, instead of only being from the soil-pipe alone, would in this case be from the drain also. This is anything but an improvement upon plans published years ago.

* Why not keep the drain out of the house altogether, and so save both risk and gas expense?—W. P. B.

3rd. Fitting up a bath without a water-trap on its waste-pipe is another mistake, and so with the lavatory basin.

4th. No trap on the sink in the scullery is another fault.

5th. Putting in an apparatus to blow off stinking air in a town house continuously, even when there was no wind to carry it off, is hardly a plan to be recommended at the present day, when plans for the prevention of the pollution of the atmosphere of our towns and cities are under consideration.

I might say more, but I should first like to see what Sir Henry Cole has to say in reply to the foregoing criticisms. W. P. Buchan.

THE LATE MR. E. C. SAYER.

A few particulars as to the career of the late Mr. Edwin C. Sayer may not be thought an undesirable record, inasmuch as he was an individual much known and esteemed by the architectural profession, to which he belonged.

He was a native of the West of England, where he resided until the completion of his term of articleship in Bristol. Coming to London in the early part of 1841, his first engagement appears to have been as an assistant among the already numerous staff in the office of Messrs. Scott & Moffatt, of Spring Gardens, — subsequently that of Mr. (Sir Gilbert) Scott alone. In the May of that year I myself entered the same office, in a similar capacity, as did also Mr. J. K. Colling in the following November; and thus commenced an acquaintanceship with the deceased which was maintained to the last. Upon quitting Messrs. Scott & Moffatt's, he migrated temporarily to Norwich, to the almost equally busy office of Mr. John Brown (familiarly known as "Brown of Norwich"), and then, returning to London, he became attached to that of Mr. Sydney Smirke, where he met with the late Mr. James Wylson, and thus, in conjunction with Mr. Wylson, Mr. Colling, and myself, he, towards the close of the year 1842, helped to found the "Association of Architectural Draughtsmen," "reconstructed" in 1847 as the "Architectural Association," now so flourishing and useful. Of this original association Mr. Sayer was the first secretary, and a letter from him on the subject appeared in the *Builder* of January 8th in the present year.

There was yet another distinguished London office with which he became connected, viz., that of the late Mr. Pennethorne, of Whitehall, whom he assisted in many important professional works. His concluding engagement of this nature was in a smaller sphere, but one that again appeared well to suit his predilection for Classic rather than Gothic art. As right-hand man to the late Mr. Humbert, of Fitzroy-square, the architect of the Royal Mausoleum at Frogmore, and also at Sandringham for the Prince of Wales, his abilities were largely exercised in the carrying out of both these works; and at Mr. Humbert's decease he had the satisfaction of finding that a handsome legacy from that gentleman was a farther proof of regard for his faithful service. Such instances are, unfortunately, too rare.

Being always a devoted admirer of Sir Christopher Wren's works, Mr. Sayer procured access to the model of the first design for St. Paul's Cathedral at a time when it was less known than it is at present; and in his leisure hours he prepared a series of large and careful drawings, to scale, of that proposed edifice. These he cherished for a long while in his own possession, but I think that a few years ago he presented them to the Institute of British Architects.

Owing to the peculiar bent of his disposition, and to his naturally reserved habits, he was never ambitious to set up in practice for himself, preferring to work with and for others, until some time ago he retired from professional life, to devote himself more to those literary pursuits which were ever his special delight. He was a great reader of standard books in various languages; also of the best productions of a lighter kind. Being, moreover, a good logician, and possessing a retentive memory, his conversation was invariably instructive and entertaining; always greatly appreciated by the limited circle of friends to whom he chiefly confined himself in his later years. But there is little doubt that this comparative isolation had a more injurious effect on his sensitive and nervous temperament than he was aware of; thus tending to hasten his death, which occurred on the 23rd ult., at the age of sixty-three, and in the house where he had lived for nearly twenty-five years. J. Drayton Wyatt.

CASE UNDER THE BUILDING ACT.

At Worship-street Police-court, on the 22nd ult., before Mr. Hannay, Mr. W. H. Middleton was summoned by Mr. Frederick Meeson, District Surveyor for East Hackney (North) for 15*l.* 1*s.* 4*d.*, for expenses incurred under the 47th section of the Metropolitan Building Act 1855, in rebuilding walls of less than the minimum thickness allowed, and in raising stories of less than the minimum height, of a block of five houses at the corner of Castlewood and Mountfield roads, Craven-park, Stamford-hill.

The works were carried on in December and January last, at which time the defendant was owner; but he became bankrupt in January, shortly after the completion of the works. An account of the expenses named was served on him in June last.

The magistrate considered the defendant was not liable, as he, being then a bankrupt, could not be said to be in receipt of the rents or profits when the account was served on him. Summons dismissed.

BUILDING BY-LAWS.

BUILDINGS FOR RAILWAY PURPOSES.

At Highgate, Alfred White, builder, of 152, Central-street, St. Luke's, appeared before Mr. Lermitte, Colonel Stedall, and Mr. Homan, to answer two adjourned summonses, taken out by order of the Finchley Local Board of Health, charging him, under that Board's by-laws, with failing to give written notice to the Board of his intention to erect certain buildings on land belonging to the Great Northern Railway Company, adjoining Torrington-park Station, Finchley, and failing to send in complete plans or sections of such buildings; also with erecting the buildings without enclosing them with properly constructed walls. Mr. Stevens, solicitor to the Board, prosecuted; Mr. Dodd, barrister, instructed by the solicitors to the Great Northern Railway Company, defended.

The buildings erected were an office built of wood, and a corrugated iron stable, both used by Messrs. Rickett, Smith, & Co., coal merchants, and, as they were within 30 ft. of adjoining villa premises, Mr. Stevens contended that they came within the provisions of the Board's by-law, and that, not being for the purposes of the railway company, exemption could not be claimed under the 157th section of the Public Health Act. Mr. Dodd contended that, both under the company's private Act and the Public Health Act, the buildings were exempt. They were erected for Messrs. Rickett, Smith, & Co. by the company, but might have to be extended to meet the requirements of other coal merchants, who otherwise might appeal to the Railway Commissioners, or they might have to be removed altogether, to extend the station. He further contended that the by-law must be considered legally "bad" in this case, as it was unreasonable to require wooden or corrugated iron structures to be put together with good mortar. No demise of the land had been made to Messrs. Rickett, Smith, & Co.

The Bench considered that the buildings were exempt, but formally postponed their decision to give Mr. Stevens an opportunity of appealing, if instructed to do so.

PROVINCIAL NEWS.

Weston-super-Mare.—The new Masonic Hall here has just been completed. It is situated at the corner of the Waterloo Boulevard and Longton Grove-road, and has been built from the designs of Messrs. Hans Price & Wooler, architects, of Bristol, in the Late Tudor style. It is built entirely of Bath stone, laid in irregular and narrow courses. At the corner nearest the boulevard is a tower rising to some altitude, and having a projecting embattled and panelled cornice, resting upon bold corbels. Above is a low, half-timbered roof, terminated by a flattish-pitched spire, whose roof is covered in by oak shingles, and surmounted by a gilded copper vane. In sunken quatrefoil panels along the upper part of the façade facing Longton Grove-road are shields bearing various Masonic emblems. The two entrances are moulded and carved, particularly the main one. Over this is a recessed and canopied niche, whereon stands a sculptured figure, in Kenton stone, of the patron saint, St. Kew. This statue is the work of Mr. Harry Hems, of Exeter, by whom also all the carving in stone and wood throughout the building has been done. The lodge-room has an opened timbered roof, ornamented by carved wooden bosses. The hall has been built by Mr. S. Taylor Harvey, of Bristol, within the time allowed by the contract conditions.

Whitfield Court (Herefordshire).—During the past two years and a half very extensive alterations and additions have been in progress at Whitfield Court, the seat of Mr. and Lady Katharine Clive. The work, which has now been completed, has been carried out from the plans and under the superintendence of Mr. Cheiake, architect and county surveyor. In the year 1853 the late Rev. Archer Clive found it requisite to increase the size of Whitfield by the erection of a new entrance-hall, with three bedrooms over, and offices below; and this block of buildings was termed the east wing. This wing has now been raised one story higher, so as to give three more rooms. But the most conspicuous change in the mansion consists of its enlargement by the addition of a new block on the south-west. The principal room in this new portion is a drawing-room, measuring 44 ft. long by 24 ft. 6 in. wide, with a height of 22 ft. in the clear, in addition to a large octagonal bay window. The space over this apartment is divided into three or four rooms. The walls of this block are 3 ft. thick, faced with stone from the estate, worked in their courses, and lined with brick inside, so as to guard against damp or uneven temperature. The approach from the library to the drawing-room is through a secret book door, and behind a triple arcade, opening immediately into the drawing-room. This arcade consists of three arches, resting upon twisted columns with caps and bases, the latter being supported by a carved plinth. Two of the arches have a moulded transome, separating them from the arcading below, whilst underneath the transome are some old Italian cut velvet hangings, to screen the library door from the drawing-room. There is also an entrance from the first landing of the principal staircase to the drawing-room through a richly-carved door, which Mr. Clive purchased in Florence. This door was sent to Whitfield, and designs made for having it encased in jambs to match, including a pierced tympanum. This portion of the work, as well as the book-shelves and the arcade from the library, was executed by Signor Borrani Piazza, Santa Maria Novella, Florence. It is worked in Italian walnut, polished, with the mouldings relieved by gold. The floor of the drawing-room is of the parquetry pattern, and was constructed in Venice and sent to England in pieces of about 2 ft. by 2 ft. All the rest of the woodwork is teak, with the exception of the massive chimney-piece, which is constructed in wainscot oak. A new staircase in wainscot oak is one of the principal features of the new work. A large reservoir, capable of containing 25,000 gallons of water, has been constructed on what is known as the Sheep Walk, and is intended to furnish a supply of water to the house, and will also enable the mansion to be flooded in case of fire. Hydrants are fixed at intervals round the house, and internally, at the most exposed parts on each floor, large service-pipes with taps and hose are placed. The whole of the water-supply arrangements have been carried out by Messrs. Easton & Anderson, of London, whilst Messrs. Rosser & Russell, of 22, Charing-cross, London, have furnished the structural arrangements for heating, and hot-water supply to housemaids' closets, baths, &c. Mr. James Bowers, of Hereford, has been the contractor for the whole of the works. The carving was entrusted to Mr. Robert Clarke, of Hereford, and the bell-hanging, gun-metal casements, and other works of this kind, were executed by Mr. W. Letharen, of Cheltenham.

HYDRAULIC DIFFICULTIES.

Sir,—Will some of your correspondents kindly help me out of a dilemma? Some time since I bought a house, with the intention of extending it backwards, and by excavating the basement and underpinning the walls to get 8-ft. headway in the basement-floor (there were only 6 ft. originally); but in making the extension we had to build over a well, and the water in this well rises to within 7 ft. of the ceiling, so by the time the dwarf walls, joists, and flooring are down there will be barely 6 ft. between the floor and ceiling. I must state I have an architect and builder, who advised me to have the well concreted. I accordingly had the well cleared out to the bottom, a few stones placed there, and a pump inserted, to keep it dry, to give the concrete time to set. The latter was made of one part Portland cement, one part Plympton sand, and one part limestone chippings, well stamped down, with a cavity in the sides of the well, 9 in. back, to allow the concrete to have a hold. We then saw the water coming up from the hole where the pump was inserted. After thirty-six hours we withdrew the pump, and put clay in the hole, then Portland cement and sand mixed; but in less than fifteen minutes the water was up between the concrete and shillet, or soft rock, and the water is up now to its original level. I must state the basement-floor is about level with the main drain,—perhaps a little below it,—so that it is impossible to carry it into the drains. My architect and builder seem to be at their wits' end, and I appeal to you.

Greenhorn.

Leominster.—A Wesleyan chapel at Steen's Bridge, Leominster, has been opened, the "architect and builder" being, we are told by a Hereford paper, Mr. Hine, of Ludlow.

CHURCH-BUILDING NEWS.

Dearham.—A bazaar has been held at Maryport to raise funds for the restoration of the ancient parish church of Dearham. The work is to be entrusted to Messrs. Cory & Ferguson. It appears that the church has been in tolerably good condition up to 1847, but in that year, owing to the working of a mine in the vicinity of the church, the building began to crack in various places, and the lintels were broken. Mr. Charles Ferguson, in his report on the condition of the church, says,—"The interior of the church is in a deplorable condition. The floor is damp and much decayed; the seats are rotten; the plaster is much injured by damp; and the principal lintel at one of the windows has entirely decayed and fallen out of the wall, leaving the wall above it unsupported except by the mortar." The cost, including provision for increased accommodation, is estimated at 1,750*l.*

Battersea.—On the 10th ult., the Bishop of Rochester dedicated the newly-erected Church of St. Michael, Battersea. The building is situated in Bolingbroke-grove, Wandsworth-common, and is constructed of red and yellow brick, with a timber roof covered with red tiles. It consists of a nave, chancel, and two colonnades, the latter separated from the nave by arcades having octagonal columns of marble, surmounted by Portland stone capitals. The floor is of wooden blocks, and the pews are of the low doorless pattern. It will accommodate about 750 persons, and its total cost will be about 4,500*l.*, of which all but 800*l.* has been contributed by the relatives and friends of the late Rev. H. B. Verdon and Mr. Philip Cazenove, to whose memory the church is erected. Mr. W. White, F.S.A., is the architect, and Mr. J. D. Hobson was the builder.

Sidbury.—Holy Trinity Church, Sidbury, near Bridgnorth, has been re-opened, after restoration, which has been carried out under the direction and to the drawings and specifications prepared by Mr. R. Griffiths, architect, Stafford. The general fabric was found to be in a very dilapidated condition, the whole of the roof having been stripped, and the mortar removed from all the exterior walls. The stone work has been repaired, and partly rebuilt in herring-bone to correspond with the old work. The old timbers in the roof (where required) have been removed, and the space between the rafters plastered and left visible, including the bold oak principals. The roofs are covered with tiles obtained from the Billingsley brickyard. The chancel has a pitch-pine boarded ceiling, formed in panels with moulded ribs. The old porch has been taken down, and a new one built to correspond with the other portion of the work. The stone for the masonry and walling, raised near the church, is the gift of Mr. C. R. E. Cresswell, Sidbury Hall. A new window has been added to the north side of the nave, and the whole of the jambs to the doors and windows thoroughly cleaned down. An entirely new chancel arch has been added. The old stone paving has been removed, and the aisle and chancel paved with Messrs. Maw & Co.'s encaustic tiles. The whole of the seating in the chancel and nave is in pitch-pine, with moulded bench-ends. The pulpit and reading-desk have been reconstructed with the old oak framing, with carved panel fronts. The ancient font has been restored and cleaned. The windows have been re-glazed with cathedral glass by Mr. John Davies, of Shrewsbury. The whole of the work has been carried out by Messrs. Nevett Brothers, contractors, Ironbridge.

Mathern.—Mathern Church, near Chepstow, remarkable as the burial-place of Theodrick, or Teudrick, the hermit-king of Glamorgan, is now undergoing a thorough restoration, and the following interesting information has been furnished by Mr. William White, of Abergavenny, the contractor for the work:—Upon an examination being made of the south wall of the chancel, it was found that the heavy timbers of the roof had thrust the wall 9 in. out of the perpendicular. It was then decided to put the wall back to its former position without taking it down. To accomplish this a strong barrier was erected inside, perfectly upright, and close to the base of the wall. A groove was then cut on the inside at the base, wedge shape, the whole thickness of the wall, and with a little pressure from the outside with screw-jacks, the wall gradually recovered its perpendicular, without the displacement of a single stone; the groove was then underpinned, and the barrier removed. Upon excavating at the base of this wall, under the tablet of King Theodrick, a stone coffin was found, partly filled with dry mould and some bones (supposed to be those of the king). The stone coffin was removed to a place of safety for re-interment. Its dimensions are 5 ft. 7 in. long, exterior, and 5 ft. 3½ in. interior; its width is 20 in. exterior, and 16 in. interior; the depth, 11 in. exterior, and 6 in. interior.

Salhouse.—The restoration of the somewhat singular church of Salhouse is progressing, and (according to the *Norwich Argus*) the building will be re-opened in November. Salhouse is some five miles north of Norwich. Its parish church, dedicated to All Saints, is a plain old building, consisting on plan of chancel, nave, north aisle, and tower. This tower has little affinity with the rest of the church. The late Sir G. Gilbert Scott, R.A., was of opinion that when it was built it was intended to considerably enlarge the church, and he based this opinion upon the fact that the tower in question did not stand in the centre of the nave line, but was centered with the south wall of the nave upon the one hand, and the north wall of the north aisle on the other. By this treatment, he thought, the old men intended to raise the latter wall to the height of the former, construct one roof over the whole, and probably add a north and south aisle. The buttresses that flank each side of the tower quite support this theory. The scheme was never carried out, however; after building some 60 ft. high, and ere the natural terminations of the angle buttresses were reached, a temporary roof was put on, and thus it remained. In the present restoration nearly all the south wall of the nave has been rebuilt in rubble work as before, the old roof of the tower has been removed and recovered, and the steps leading to the tower repaired. The nave roof has been stripped of its thatch, and a strong one of English oak has been erected. This is covered by a layer of reeds to a thickness of about 15 in. A south porch has been added,—the walls being of Trapp flint and the dressings of Ancaster stone. Over the entrance is a richly-carved niche, and the apex of the gable is crowned by a foliated cross in stone. There are three new two-light windows in the south aisle, and one has been put in the chancel. The old remaining bits of ancient stained glass have all been carefully preserved and re-used. The stone carving has been executed by Mr. Harry Hems, of Exeter; the builder is Mr. George Dobson, of Colchester, his general foreman being Mr. George Stow. The works are being carried out from the designs and under the immediate superintendence of Mr. John Oldrid Scott, architect, Spring-gardens, London. The estimated cost of the restoration is 3,500*l.*, but further works are contemplated. The old carved oak screen especially should be cared for.

Bistre.—On the 20th ult. the parish church at Bistre was re-opened, after restoration. The vicar (the Rev. J. N. Evans) found on entering upon his work that the building was in a very unsatisfactory state, and he determined to effect its restoration. The amount required for the restoration was 700*l.*, and the greater part of this sum having been raised, designs were called for, those of Mr. Spaull, of Oswestry, being eventually accepted. The work, which was placed in the hands of Mr. J. Williams, builder, of Buckley, was commenced in May last. The gallery at the west end has been removed, as well as the whole of the interior fittings of the church. The apse at the east end has been raised and ceiled with wood, and the east window, which previously was level with the communion-table, has been raised and filled with stained glass by Messrs. Ballantyne, the subject being our Lord in the garden of Gethsemane. This window is the gift of the Pemberton family of Plas Issa. The last bay at the east end of the church has been raised two steps and rearranged. The choir, reading-desk, and vestry are at the south side of the transept, while the organ is on the north. The body of the church has been filled with open seats, capable of accommodating 400 worshippers; while the aisles have been laid with tiles, and the choir and sacrarium with encaustic tiles from the Pen-y-bont works of Mr. J. C. Edwards.

Waterworks, Milton-next-Sittingbourne.—The works for the water supply of this place have been completed, and were formally opened on the 27th ult. They have been carried out by Mr. Henry Robinson, C.E., of Westminster; the contractor being Mr. George Torkington.

DISSENTING CHURCH-BUILDING NEWS.

Birkenhead.—The Unitarian Church, Charing-cross, Birkenhead, was re-opened on the 4th ult., after various alterations. A new chancel, 17 ft. 6 in. by 12 ft. has been added, with organ-chamber and vestry attached, and having a window filled in with stained glass, the subject being "A Vision of St. Louis on the Shores of Palestine." New glass has been put in all the old windows, and the whole church has been refurnished and decorated. The lecture-hall below has been nearly doubled in size, and cloak-rooms and conveniences added. The whole work, which has been executed by the following contractors, has cost about 1,850*l.* The general contractors for the works were Messrs. Legge & Co. The stained-glass window, ornamental tiling to reredos, and all the decorative work, were by Messrs. Shrigley & Hunt, of Lancaster and London. Mr. Rogerson, of Liverpool, was the sculptor of the reredos; the gas-standards are by Willis & Co.; and the floor-tiling by Craven, Dunnill, & Co. The whole has been carried out under the direction of Mr. James N. Crofts, architect, Liverpool.

North Hykeham (Lincolnshire).—The foundation stones of a Wesleyan chapel and schools have been laid here. The designs of the building were prepared for the builder by Mr. W. Mortimer, architect, Lincoln. It will cost 500*l.*, and will seat 200 people.

Walsall.—A new Presbyterian church is in course of erection here. The church, with schools, vestry, and other accommodation for congregational purposes, is situated at the junction of Hatherton-street and Darwall-street. The church is planned with the principal gable fronting Hatherton-street, and in this will be placed the main entrance. At the angle of the front next to Lichfield-street will be placed a tower 14 ft. square at the base. The lower story will contain the gallery entrance and stone staircase, and above this will be the bell-chamber. The upper part of the tower, exteriorly, will be gabled and pinnacled, and surmounted by an octagonal spire, rising to a total height of about 100 ft. from the ground to the top of the finial. The side elevations of the church to Darwall and Lichfield streets show each four stone traceried windows, two of two-lights and two of three-lights, the latter of which will be carried up to form gablets. The interior of the church will be divided into quasi-nave and aisles by the introduction of a light arcading of timber supported on iron columns. This has been rendered necessary by the adoption of a wide span roof, consequent upon the proportions of the site. The internal dimensions of the church are:—Length, 63 ft. 6 in.; breadth, 45 ft. 9 in.; height, from floor to ceiling in centre, 38 ft. Sitting accommodation will be provided on the ground-floor for over 400 adults; and, including the additional sittings in the gallery over the main entrance, the building is computed to accommodate about 500 persons. The school buildings will be placed at the rear of the church, with the end gable fronting Darwall-street. They will comprise a large room, 32 ft. 6 in. by 24 ft. wide, and four class-rooms, varying in size from 12 ft. by 7 ft. 6 in. to 15 ft. 6 in. by 11 ft. 6 in., thus securing a total accommodation for upwards of 200 children. It is proposed to warm the whole of the buildings by hot air, and this portion of the contract has been entrusted to Messrs. Haden, of Trowbridge. The buildings have been designed in the Gothic style, of the early fourteenth-century period, and are to be constructed of bricks, faced on the fronts with best local pressed bricks. The jambs, moulds, plinths, and strings are also of brick; and the window tracery, sills, mullions, copings, &c., are to be of Bath, Penkridge, and Codsall stone. Interiorly, the church is to be lined with pressed red bricks up to the height of the window sills, thus giving a deep base or dado of colour. Above this the lining is to be of pressed buff bricks, tuck-pointed with red mortar, which it is believed will produce a very clean and cheerful effect in the internal appearance. The interior of the schools is to be lined with brick, neatly pointed, and coloured and painted in approved tints. The woodwork throughout is to be of the best Baltic fir, and the internal fittings are to be stained and varnished. The contract for the various works has been taken by Messrs. William Trow & Sons, of Wednesbury, and they are now proceeding with the buildings, from the plans and under the superintendence of Messrs. John Cotton & H. H. McConnal, architects, of Birmingham and

Walsall, whose joint designs were selected some three years ago. The cost of the buildings, including lighting, warming, and furnishing, is estimated at about 3,000*l.*

STAINED GLASS.

Chelmsford.—A window has been placed in St. Mary's Church as a memorial of the late Miss Ann Baker. Messrs. Clayton & Bell have supplied the window, which is of two lights, and illustrates the texts, "I was an hungered, and ye gave me meat," and "I was sick and ye visited me."

Shoeburyness.—A memorial window has just been placed in the parish church of St. Andrew's, Shoeburyness. The glass is from the firm of Messrs. Cox, Sons, Buckley, & Co., of Southampton-street, Strand, and the window is put up to the memory of Major Lambert, late of the Royal Engineers. The window illustrates passages in the "Pilgrim's Progress," and is intended to represent the Christian pilgrimage.

Dewsbury.—The large south transept window of St. Mark's Church has just been filled with painted glass "in loving memory of (the late) Williamson Metcalfe, of Elmwood House." The window has four chief openings. Each is divided into two compartments by bordures and panels of rich ornament, thus allowing the introduction of eight figure subjects. The groups are richly coloured on a diapered ruby background. The intervening and inframing spaces of ornament are kept chiefly in white and dull blue, with here and there a little golden stain. The widow is the donor of the window, and Messrs. Powell Bros., Leeds, executed it.

VARIORUM.

Beckett's Provincial Builders' Price-Book and Surveyors' Guide (E. & F. N. Spon) is issued on the ground that existing Price-Books are London books, and not applicable to the provinces. If all provincial towns adopted the same system of measuring and the same prices, there would be greater force in this observation than, as it seems to us, there is. The Liverpool Building Act is appended, and the Manchester By-laws, and the book will doubtless be found useful by many. We are bound to say, nevertheless, that we would rather see endeavours made to bring about more general uniformity than to confirm existing divergences. Comparing prices with those given by "Laxton," considerable differences in various items, the provincial being lowest, are found; as to day-work, however, ½d. per hour less is all the difference stated,—10d. per hour, that is, instead of 10½d. —— The October number of the *Antiquary*, a very good one, commences with a short "Study on Poet's Corner, Westminster Abbey," by Henry Poole, Master Mason of the Abbey. The Rev. H. N. Ellacombe contributes the first portion of an elaborate paper on "Shakspeare as an Angler."——"Gleanings from Popular Authors, Grave and Gay," of which part I. comes to us from the ever-active Cassell, Petter, & Co., is intended not alone as a half-hour book, in which will be found some of the best sayings of the best authors, but as a treasury of pieces suitable for reading in public. The illustrations are effective.

Miscellanea.

The Orphan Asylum Building at Clapton.—We are informed that this large and substantially-built structure, erected in 1823, and abandoned a few years since by the removal of the inmates to the new asylum at Watford, is likely to be taken for the purpose of a training home or homes for the young men and women "cadets" of the "Salvation Army." The once beautiful wooded lawn and garden in front and rear of the Asylum were recently parcelled out into building lots, and streets of houses have been erected thereon, and a number of them are at present occupied.

Statue of the Late Mr. George Dawson.—A statue of the late Mr. George Dawson has been unveiled at Birmingham. The statue, which is of white Sicilian marble, is 6 ft. 6 in. in height, and the late Mr. Dawson is represented in a standing attitude, in the act of addressing an assembly, with his right hand crossed on his left. On the four sides of the canopy there will be four medallions of Sicilian marble, consisting of the heads of Shakspeare, Carlyle, Bunyan, and Oliver Cromwell. The work has been executed by Mr. Woolner, R.A.

Proposed Boulevard round London.—The prospectus has been issued of a "pioneer company" to be formed privately for the purpose of providing funds to obtain the necessary Parliamentary powers to make a boulevard round London, the work to be carried out by a public company to be formed when the necessary powers to execute it have been secured. The proposal emanates from Mr. E. L. Paraire, architect, and if carried out will, according to the prospectus, comprise a broad and continuous roadway about twenty-five miles in length, with wide footpaths on each side, planted with trees. Powers will be taken to lay down tramways so soon as roads of sufficient length to be remunerative are constructed. The boulevard will be made in sections, and will traverse the whole of the suburban districts of the metropolis, at an average distance from St. Paul's of about five miles on the east, and four miles on the north and south. Commencing on the north side of the Thames at Cubitt Town, it will pass by Poplar, Clapton, Hampstead, Kensal New Town, to Hammersmith, where it will be joined by one of the bridges over the river, thence to New Brompton (?), Clapham, Peckham, and Greenwich. The greater part of the land required is now free from buildings, and said to be available for the proposed work. The sum to be obtained for the frontages to the boulevard will, it is believed, cover the outlay required for the construction of the works. It is estimated that the ultimate expenditure will amount to 2,500,000*l.* Roughly speaking, the boulevard, as shown on the plan sent to us, will enclose the metropolis in an irregularly shaped oval. The east end of this oval, we notice, is marked on the plan "not surveyed," and it is here that apparently serious obstacles present themselves. On the south side of the Thames Greenwich Park seems to be in the line of the proposed boulevard, and on the north side, the docks at Blackwall appear to offer an obstruction. Is it proposed, as part of the scheme, to erect a bridge across the river at Greenwich? Nothing is said about such a bridge in the prospectus. Mr. Paraire has for many years been considering the subject.

Fire-Extinguishing Apparatus at the New Savoy Theatre.—In a previous issue we mentioned that Messrs. Merryweather & Sons, of Long-acre, had fitted the new Savoy Theatre with fire-extinguishing appliances, and we think it may interest our readers to know that the apparatus differs from any previously fitted inside private buildings in the fact that the hydrants are of an improved form, having a thread which is known as the new Metropolitan Brigade Gauge, and which enables the hose to be more rapidly connected or disconnected with an impossibility of the threads becoming "fouled." The hose is of canvas, tanned, and rubber lined, so as to render it waterproof, and the couplings and nozzle-pipes are also of the new-pattern round coarse thread.

Cheap Cottage Building.—Mr. Villiers Stuart, M.P., in a letter to the Lord Mayor of Dublin, proposes to offer a prize of 50*l.* for the model of the best labourer's cottage, the construction of which should not exceed 52*l.* 10*s.*, which would enable it to be let at 1*s.* per week. Mr. Stuart suggests the model should be arranged in the forthcoming exhibition of Irish industries side by side with the one which Mr. Johnson, of Kanturk, secretary to the Labour League, proposes to send of a Limerick labourer's cabin of the present time, "thus placing in instructive contrast what Irish workmen's dwellings so often are and what they might be."

Tenders at Croydon.—Complaints are made that the Guardians of Croydon Union, after inviting tenders for painting the outside of the workhouse, have given the work to the tradesman they have been in the habit of employing, although the tender of an equally competent person was much lower.

The Annual Dinner of the Builders' Benevolent Institution is announced to take place on Thursday, November 3rd, when the President, Mr. ex-Sheriff Burt, of the firm of John Mowlem & Co., will, we trust, be supported by a large number of the friends of the Institution.

New Southport Market.—The revolving shutters mentioned in our account of this building were supplied and fixed by Clark, Bunnett, & Co. (Limited), who have also received instructions from the Corporation of Oxford to fix their patent noiseless steel shutters to the extension of their city markets.

Chemical Fire Engines.—A practical demonstration of the powers of Dick's chemical fire-engines to arrest fires in their early stages was given last week, the experiments being made by permission of the City Lands Committee on vacant ground near the Thames Embankment. Mr. James Sinclair, of Leadenhall-street, in explaining the trial to which the engines would be put, remarked upon the importance of dealing with a fire before it had got hold of a building. The extincteur "Fire Queen," with which an experiment was first to be made, was filled with an innocuous chemical containing a large porportion of carbonic acid in its composition. At the top of the extincteur and within was a bottle of sulphuric acid, and in order to put the engine in readiness to extinguish a fire it was only necessary, by giving a smart tap on a rod, to break the bottle of sulphuric acid. As soon as this was done carbonic acid was set free from the chemical liquid, and a cock being turned the pressure of the carbonic acid gas formed within the extincteur forced the water out in a strong jet, the water carrying with it a large quantity of carbonic acid. The effect of the carbonic acid on a fire would be seen by the almost instantaneous extinguishing of the burning combustibles that were to be experimented upon. A large pool of tar and petroleum was first set on fire, and the flames put it out in sixteen seconds. The experiment was repeated and the fire extinguished in ten seconds from the time the stream from an extincteur was directed upon it. Other experiments, equally satisfactory, followed.

Pictures for Birmingham.—Mr. Joseph Nettlefold, managing director of the well-known firm of Nettlefolds (Limited), has announced in a letter to the Mayor his intention of bequeathing to the town of Birmingham, for exhibition in the new local art gallery, his valuable collection of oil paintings by David Cox. The paintings, which are twenty-five in number, comprise several of the painter's most admired works, including the "Skirts of the Forest," "Waiting for the Ferry," "The Hayfield," "Change of Pasture," "Rhyl Sands," &c., and are of the estimated value of from 25,000*l.* to 30,000*l.* Among the conditions accompanying the gift will be these:—"That the pictures from the time they are delivered be open for exhibition to the public free of all charge on every day in each year, and not closed earlier than 8 p.m., except for a period not exceeding fourteen consecutive days in each year, when the gallery may be closed for cleaning." "That the room in which these pictures shall be exhibited be lighted in the evenings by the electric light." The offer has been gratefully accepted.

Architecture: University College, London.—Under Professor T. Roger Smith, three courses of evening lectures will be given this session at the College, Gower-street. The subjects treated remain substantially the same as in previous sessions, but such alterations will be made in the mode of dealing with them as, in the opinion of the Professor, may render the lectures useful to students preparing for the Associates' Examination at the Royal Institute of British Architects, or the District Surveyors' Examination, as well as to pupils and other students of architecture; and a public introductory lecture, explanatory of the course and with suggestions as to modes of study, will be given at the College, by Professor Roger Smith, on Monday next, 10th October, at six p.m., admission free. Architects and students of architecture are particularly invited to attend. The full syllabus can be obtained on application to the assistant-secretary at the College.

The Mersey Tunnel.—On the recommendation of the works committee, the Mersey Docks and Harbour Board have assented to a proposal of the Mersey Railway Company to sink a second shaft on the Birkenhead side of the river, so that the works of the proposed headway and main tunnel may be proceeded with simultaneously.

Messrs. S. Owens & Co., of Whitefriars-street, have issued a new section (No. 1) of their Illustrated Catalogue, containing prices of pumping machinery of every description for steam, water, or wind power, self-acting hydraulic rams, &c. It will be found useful.

A Fenman writes, with reference to Mr. G. Hamit's machine for cutting water-weeds, noticed in our last week's impression, page 420, that it is not for "roading," but for "roding." In fen language, *to rode* is to remove weeds from watercourses.

TENDERS

For the erection of new Baptist Church, Handsworth, near Birmingham. Mr. John P. Osborne, architect:—

Moffat	£7,027 0 0
Garlick	6,950 0 0
Barnsley & Son	6,750 0 0

Hatfield, Blackheath	1,350 0 0
Higgs & Hill, South Lambeth	1,346 0 0
E. Banks, Lewisham (accepted)	1,345 0 0

For new Mission Church, Algernon-road, Lewisham:—

Colls & Sons	£3,678 0 0
Holland & Hannen	3,611 0 0
Jerrard	3,571 0 0
Goddard & Sons	3,563 0 0
Blake	3,555 0 0
Perry & Co.	3,485 0 0
Patman & Fotheringham	3,375 0 0
Havell	3,320 0 0

For villa residence, Orbel-road, Surrey-lane, Battersea. Mr. C. F. Fenton, architect:—

F. Warr, Neville-road, Croydon	£606 0 0
T. Beanchamp, Brentford End	554 0 0
R. P. Barnes, Bedford Park, Chiswick	547 0 0
T. Hiscock, High-street, Hounslow	491 0 0
R. Squelch, Hurmur-road, Egham	427 0 0
W. B. Prentice, Devonport-road, Shepherd's-bush (accepted)	390 0 0

For additions and alterations to Collingwood Park, Camberley, for Colonel Lampriere. Messrs. Harrison & Cooper, architects:—

Martin Wells & Co., Aldershot	£1,205 0 0
William Watson, Ascot Heath	1,183 0 0

For alterations and additions to 5, Wimpole-street and Harley-mews. Mr. A. E. Hughes, architect. No quantities supplied:—

McLachlan & Sons	£2,770 0 0
Simpson & Sons	2,630 0 0
Williams & Sons	2,515 0 0
Downs	2,217 0 0

For repairs, &c., to 27 and 27A, Sackville-street. Mr. Wimperis, architect. Quantities supplied:—

Curtis	£1,218 0 0
Patrick & Sons	1,215 0 0
Scrivener & Co.	1,199 0 0
Fish	1,174 0 0
McLachlan & Sons	1,124 0 0
Langmead & Way	1,067 0 0
Hatfield & Sons	980 0 0

For lowering, widening, sewering, metalling, &c., a portion of Shepherd's-hill-road, for the Hornsey Local Board. Mr. F. de Courcy Meade, surveyor:—

Walker, Upper Holloway	£2,879 0 0
Josh. F. Meaton	1,450 0 0
Pizzey	1,397 0 0
Daymore	1,389 0 0
McKenzie, Williams, & Co.	1,338 0 0
Strachan & Co.	1,259 19 4
Thomas Rowley	1,220 0 0
Randell & McDowell (accepted)	1160 0 0

For repairs of sea walls and construction of groynes and outfalls for the Commissioners of the Level of Tendring, Essex. Mr. Wm. Berrell, engineer. Quantities supplied by Messrs. R. L. Curtis & Sons:—

Hill & Co., Gosport	£9,632 0 0
J. Botterill, Cannon-street	8,103 0 0
C. Chamberlain, Littlehampton	7,073 0 0
Sarnes & Co., Crayford	6,924 0 0
E. Harrison, Peckham	6,350 0 0
R. Tyler, Kensington	5,893 0 0
Saunders & Son, Deedham	5,830 0 0
A. F. James, Hythe	5,801 0 0
G. Hunter, St. Peter's Park	5,678 0 0
J. Moran, Harwich	5,641 0 0
R. Walker, Lynn (accepted)	5,132 0 0

For enlargement and repairs to Hawkwood, Chingford, Essex. Mr. F. Boreham, architect:—

Morter (accepted)	£1,547 0 0

A Chaldean Temple.

DISCOVERIES which have resulted from the expedition of 1880-1881, which that able explorer, Mr. Hormuzd Rassam, has just concluded in the Tigro-Euphrates Valley, will be of particular interest to the students of ancient architecture and archæology, as they afford us valuable information on both of those subjects. The explorations carried out by Sir Henry Layard and others on the ruins of ancient Nineveh have furnished a considerable number of data on which the architect can base his restorations of these ancient cities, and the learned researches of Mr. James Fergusson and others have done much to place before us the appearance which the vast palaces of Assyria's kings presented to the eyes of those who visited living Nineveh. The explorations at Nimroud, the ancient Kalakh, the capital of the Middle Assyrian empire, have restored to us numerous examples of the art of Assyria at a time contemporaneous with the building of the first temple of the Jews, while the richer remains from the palaces of the Sargonide kings buried beneath the mounds of Koyunjik or Khorsabad afford us examples of the art and architecture of Assyria at the period of its highest development. From the monuments recovered and the buildings explored, the student has been able to gain a considerable knowledge of the progress which the Assyrians made in the construction and decoration of their palaces and temples. Still, however, there was a great desire for some information as to the earlier stages of the nation's art development, and especially for some examples of the earlier art of the Southern empire of Chaldea, the land out of which Assur went forth. The more we examine the art and the civilisation of the Assyrian empire, the more strongly is the fact of the deep indebtedness of the Assyrian to his Chaldean instructors impressed upon us. The letters in which the history and legends of the empire, and the accounts of the works carried out by the kingly builders in the construction of palaces and temples are recorded, were first taught to the receptive Assyrian by the Chaldean; the first problems of mathematics and science which enabled him to so accurately construct the chambers of his palaces and the main basis of his building construction, were all first learned in the schools of Chaldea.

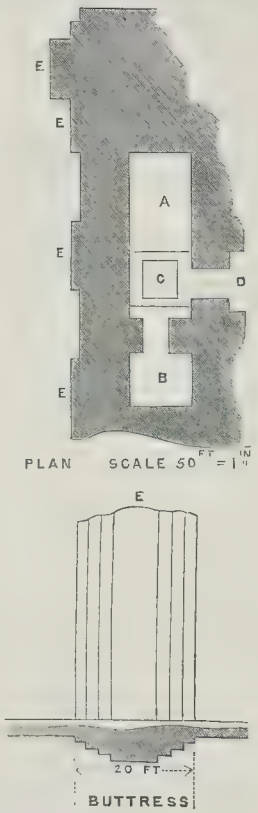
There has, therefore, long been a desire among students of the archæology of Western Asia for some example of purely Babylonian sculpture, and for the discovery of some fairly preserved edifice, either palace or temple, which might afford us a basis for the study of Babylonian architecture. Hitherto the explorations in Babylonia, with the exception of those conducted by the late Mr. Kennet Loftus, have been signally void of results in the fields of art and architecture; and the engraved cylinder seals, numbers of which are to be found in nearly all the national collections, were almost the only examples of Babylonian art extant. The explorations conducted by Mr. Loftus on the ruins of the sites of the oldest Chaldean cities of Ur (Mughhier) and Erech (Warka) brought to light the remains of some of the most ancient Chaldean temples, and these served to show that a distinct style of national architecture prevailed in the Southern empire. It was also evident that this style was due to certain local peculiarities. The scarcity of stone, and the abundance of the finest brick-making clay, caused a style of construction, in which brick was the chief material employed, to be adopted, while stucco and painted plaster were the chief means of decoration. The story of the foundation of Babylon, as transmitted to us by the Hebrew writers, has preserved to us a record of this fact, in the statement that the materials used for the great tower which formed the centre of Babylon were bricks, —"Come, let us make brick,"—(Gen. xi. 3), and the durability of the structure was still further ensured by the use of kiln-burnt brick in preference to sun-dried brick. The buildings discovered at Warka exhibited some ingenious forms of decoration by the use of cones and coloured bricks, and by the employment of floriated inscriptions as decoration for walls and the capitals of columns and the cornices. It would be interesting to find if this mode of decoration by conventionalised inscriptions, which was carried to such a state of perfection by the Arabic artist scribes, was transmitted to them from the still more ancient decorators of Assyria and Babylonia. The discoveries made by Mr. Rassam in 1878-9 in the Mujelibe mound brought to light the first edifice which had been discovered on the site of the ancient city of Babylon, and the remains found afford strong proof of the accuracy of the statements of Herodotus, Diodorus Siculus, and the writer of the Book of Daniel, as to the construction of the palace residences. The large chamber or banqueting-hall discovered by Mr. Rassam, was decorated with painted walls and cornices and mouldings of plaster inlaid with fragments of coloured clays and composition. But if the discoveries made on the sites of Ur, Erech, and the capital city of Babylon, had failed to provide the examples on which a systematic study of the architecture and art of Chaldea could be commenced, the discoveries made by Mr. Rassam during the expedition which he has just concluded, furnish much that will serve to lay the foundation of such studies. The value of the remains discovered is most materially increased when we find that they come from a city whose traditions and history as a religious centre are far older than those of great Babylon.

The traditions of the city of Sippara, the great Chaldean Heliopolis, go back far into the mythic age of Babylonian history, and it is the site and ruins of this city which Mr. Rassam has found to be marked by the extensive ruins known to the Arabs as those of the mound of Abboo Hubba, "Father of a kiss," situated some six miles from the east bank of the Euphrates. While at Baghdad, Mr. Rassam heard from the Arabs of some ruins where "written stones" were to be found, situated on the banks of an ancient irrigation canal, now called Nahr Yussifieh, which we may certainly identify with the Nahr Malcha of Herodotus, which once connected the streams of the Tigris and Euphrates. It is clear that this very winding canal is not a pure work of human skill, but is rather the result of the artificial junction and clearing of two tributary streams,—the one flowing eastward into the Tigris, the other westward into the Euphrates. This stream is called by Strabo, Nahr Ragam, a name evidently of Chaldean origin. The mounds to which the Arabs directed Mr. Rassam's attention were called Deyr, and were situated on the north bank of the canal, about eight miles from the Euphrates. The excavations made in these mounds brought to light but little of importance beyond bricks inscribed with the name of the great builder, King Nebuchadnezzar the Great (B.C. 605). As bricks of this monarch are found in almost every mound in Chaldea, and as they gave no indication of the name or nature of the edifice of which they formed part, the result of the test trenches was not regarded at all as very satisfactory.* While engaged on the work at Deyr, Mr. Rassam visited some of the surrounding mounds, and his attention was especially called to a group of mounds of large size, about four miles south-west, bearing the name of Abboo Hubba; and so attractive were these dust-heaps to his experienced eye, that he abandoned the work at Deyr, and transferred his workmen to the new and more promising site, and was soon rewarded for his work.

The ruins of Abboo Hubba are situated on the south bank of the Yussifieh canal, about thirty-five miles south-west of Baghdad, and less than six from the west bank of the Euphrates. The ruins, as clearly drawn in the excellent maps of Babylonia by Col. Selby and Lieut. Brewster, at once suggest the site of some ancient town as the position of the citadel, and the lines of walls enclosing the city can be clearly traced. The line of earthen ramparts which mark where once stood the city walls enclose an area of about 4,000 yards in circumference, and in shape a perfect parallelogram, with the angles to the cardinal points.† There are severa

* The modern Arabic name Deyr would seem to indicate that these ruins were those of the ancient city of Dur-an, or Dur-el, "the Fort of God," situated in this district.

† This was the usual mode of laying out a building in Babylonia, the Birs Nimroud, the temple at Ur, and others, all exhibit this mode.



breaks in the line of ramparts, which serve to show where the gates giving entrance to and from the city were placed; and the north-east and north-west faces of the city appear to have been protected by deep and carefully-dug canals or ditches. The axis of the large mound which marks the site of the acropolis or citadel nearly bisects the city enclosure, but the greater accumulation of *débris* is on the south side of the city, and the highest point of the acropolis adjoins the western wall of the city.

Excavations were commenced on the south-west face of the mound on the highest part, and the trenches and tunnels driven into the mound * soon reached a line of walls running nearly due north and south, these were found to form the external face of a quadrangular building, one face of which was from 1,500 ft. long.

These outer walls exhibited a style of architecture or construction similar to that in use in the ancient cities of Ur and Erech, whose ruins had been explored by Mr. Loftus. The walls were of very great thickness, over 20 ft. in places, and were faced with kiln-burnt bricks, the interior being of sun-dried bricks and clay blocks, similar to the construction of the walls of the second and third cities discovered by Dr. Schliemann at Troy. The external face of these walls was divided into equal compartments by a series of buttresses, which projected about 3 ft. or 4 ft. from the face of the wall, and were 20 ft. in width. These buttresses were decorated by a series of mouldings running lengthways, somewhat resembling ploughing, the construction being similar to that of the walls of the temple of the Moon-God at Ur.† In some of the bas-reliefs, which illustrate the wars of Sennacherib and Sargon in Babylonia and Chaldea we see this mode of decoration represented. The upper portion of these external walls was entirely lost, but judging from the examples of this style of construction, which are shown on the bas-reliefs from Assyria, we may conclude that the walls were crowned by castellated ramparts. Shafts sunk in the interior of the mound, in order to penetrate into the building whose external walls were thus discovered, led to the discovery of remains which showed that the building consisted of a series of chambers and corridors built round central courts, a mode of arrangement similar to that in use in Assyria, and in the temple of Belus at Babylon. The large inner court, round which the chambers were ranged, was probably the court, called in the inscriptions discovered on the spot, the court of the Sun God,—the deity to whom the great temple was dedicated. The outer court was dedicated to this god Bel. Having penetrated into the interior of the great building, Mr. Rassam followed the south-west wall of the inner court, and after finding the doorways was able to lay bare a number of chambers and corridors. Most of the rooms were pairs,—first, a long chamber or gallery, and then leading out of this a small chamber.‡ Access to the chambers was gained by a doorway from the larger chamber into the courtyard. One especially interesting pair of chambers was uncovered which formed the temple of the Sun God, and the value of these remains will be seen when we consider that their erection was nearly contemporary with the building of the first Hebrew temple, to which in plan they present many striking similarities. In the pair of chambers discovered by Mr. Rassam, we have the temple proper, consisting of the parts which correspond to the *naos* and *cella* of Greek temples. The outer chamber measured 110 ft. in length by 35 ft. in breadth, and was entered by a doorway 16 ft. in breadth.§ At the south-east end of this larger chamber was a doorway leading into the smaller chamber or cella, the dimension of which was 35 ft. by 40 ft.‖ A second doorway led out of this smaller chamber into the priests' quarters.

The clearing out of the larger chamber, or naos, brought to light the fact that here stood the great sacrificial altar on which the victims,—sheep, oxen, and rams, were offered.¶ The existence of this altar of burnt-offering in this outer chamber would certainly seem to indicate that the construction of the naos was hypæthral or unroofed. This outer chamber corresponds to the "holy place" of the Jewish temple, the Assyrian name of which exactly corresponds to the Hebrew, being *hekal*, "the great house."** The altar, which formed the principal feature in this outer chamber, was constructed of brick, and was nearly a square of 20 ft.

The Babylonian altars appear to have been constructed with great care and exactitude, and

like the altar in Solomon's temple the Babylonian altar of sacrifice was a square. Dr. Tibhant has shown before the Oriental Congress of London that the commencement of Indian geometrical science was due to the care with which altars were constructed. We know in the Zend Avesta, and in Vedic hymns, the special care expended on the building of the altars. The smaller chamber, or cella, was called by the Assyrians and Babylonians the *parraku*,* or "divided off portion." It is important to find that this word was cognate with the Hebrew name of the veil or dividing partition in the Jewish temple. The parraku was also another name for the harem or divided off portion of the palace, and the princes were called the dwellers in the parraku. This portion of the Babylonian temples was certainly roofed, as both Assyrian and Babylonian monarchs speak of the rich cedar and gold-plated roofs, which they added to temples of Bel and the gods of Babylon. Like the Holy of Holies of the Jewish temples, the walls and ceiling of this dwelling of the god were covered with gold. The most important use, however, of this holy chamber was that of being the place in which the records and dedication deeds of the temple were placed. In the temple at Nimroud or Calah, in Assyria, which was discovered by Sir Henry Layard, the record of the building of the temple and the great deeds of the king were written on the pavement of the parraku or cella. In the temple of the war-god at Balawat, which we have already described, the foundation records were found in a cist placed near the altar. The most precious Hebrew writings, the tables of the Decalogue, were placed in the ark in the Holy of Holies, in the Jewish temple,—so in the cella or parraku of the Babylonian temples the writings were placed under the immediate protection of the god. Guided by his explorations at Nineveh and Balawat, Mr. Rassam proceeded to search for the foundation records. This inner chamber was paved with a hard composition resembling asphalte; cutting through this pavement a shaft sunk came upon the foundation records, enclosed in a cist. The cist at Balawat was of stone, but the scarcity of this material in Babylonia, which exercised so great an influence on Babylonian architecture, had caused the Babylonian priests to enclose the records in a large cist of terra cotta.

In this record-chest were three royal deeds or charts relating to donations and endowments of the temple. These records were of two kinds, such as have been fully described by us in our former article, "Babylonian Foundation-stones." The first was a stone tablet of Nabu-bal-iddina, king of Babylon, B.C. 860, the contemporary of Assur-nazir-pal and his son, Shalmanesar II. The other records were inscribed barrel cylinders of Nabonidus, king of Babylon B.C. 555. The first of these records appears to relate to the foundation of this portion of the temple, and is dated on the 20th day of Nisan, the first month of the thirty-first year of Nabu-bal-iddina, which we may place at B.C. 850. Records somewhat similar to these tablets of Nabu-bal-iddina were found at Ballawat; but there is one important difference, in the Babylon example the aid of the sculptor has been employed as well as that of the scribe to bring more clearly before posterity the greatness of the god whom the king honoured. One-third of the obverse of this tablet is occupied by a panel, with a mythological tableau sculptured in low relief. In arrangement this record-tablet presents somewhat of a similarity to the Egyptian funeral tablet, both divine or mythological figures and those of historical personages being blended in the same field. The inscription which covers the remainder of this tablet, and extends over 200 lines, is most valuable to archæologists, as in it we have a very accurate account given of the dedication of a votive statue to the temple of the Sun-God, of its construction, and the name of the sculptor who was commissioned to execute the work. In thanksgiving for a victory gained over the Sutu, a northern Elamite tribe, the Babylonian king commissioned a priest of the temple, who was also a sculptor, to make a statue of the Sun-God for the temple, and also to carve and inscribe this memorial tablet. The priest-sculptor was named Nabu-suma-iddina, and was a priest or augur of the temple of the Sun-God. The statue was made of marble, which was obtained from the city of Kar-akna, "The Marble City," on the Euphrates. Having made the statue, the artist submitted it to the king, and the inscription on the tablet reads, "The statue of the Sun-God, the great Lord skilfully he made, by the aid of Hea and Merodach, the form of the Sun-God in the house of marble, which is on the banks of the river Euphrates. Its surface he purified and raised on its seat. The King of Babylon, Nabu-bal-iddina, in his heart had imagined this statue, and he saw the design according to Nabu-suma-iddina, the priest of the temple, and inspected its form. Over the bright image and its glorious design he poured out the joyful pleasure of his eyes." The inscription thus preserved to us is very valuable, as it furnishes us with several valuable technical terms, such as the word for statue, as distinct from a bas-relief, the verbs "to carve," to cut an inscription, and the nouns, image, design, and pedestal. But the information which this valuable record gives is not confined to the inscription; for by means of the carved tablet, which forms an illustration to the text, we are able to see very clearly the nature of this image. Like the statue of Ate in Troy, it was a seated figure of the great god. Similar statues have been found in various parts of Mesopotamia, such as the statue erected by Assur-nazir-pal at Assur or Kileh-Shergat, and the most ancient example of Babylonian sculpture, the statue erected by the primitive Babylonian monarch Gudea at Zergul.* This latter statue is now much mutilated, but the inscription on its base was copied by Mr. Rassam during his expedition of 1878-9. In this statue, carved by Nabu-suma-iddina, the Sun-God is represented as an aged man seated on a throne without a back. He has long thick locks, and a beard reaching to his waist. This form of the hairy Sun-God or solar hero is common to all mythological systems. The Greek Helios was yellow-haired or long-haired; so, in like manner, was Apollo of the Greeks, Baldur of the Norsemen,

* The area is about 1,800 ft. by 1,500 ft.
† See diagram, E. ‡ See A and B. § D on plan.
‖ B on plan. ¶ C on plan. ** A on plan.

* B on plan.

* The ruins of this city were discovered by Mr. Rassam in 1878-9, and are called Tel Ho, the Mound of the Idol.

and Isdubar or Nimrod of Babylon. There is a fine figure of this hero in the Louvre at Paris, which shows the hairy character of the Solar hero. The Sun-God's image is placed beneath an arched open shrine, which bears a remarkable resemblance to a baldachino, and is clearly the class of shrine called in the inscriptions *papakhat*. The form is supported by rusticated columns, which are clearly derived from the trunks of the palm-tree, the capitals and base being Ionic, and apparently of copper or stone added, the shafts being jointed on to them. The field is occupied by emblems of the sun and moon. The seat on which the deity sits is of wood or ivory, and carved, the seat being held up by two compound figures, half men and half bulls. The mention of robes in the inscription shows that it was the custom of the Babylonians to drape their statues, and this may in some degree account for the little care expended on the carving, and for the anatomical inaccuracy which they exhibit.

One remarkable feature in this work of art is the great and painstaking attention which has been expended on the carving of the panel, almost every curl in the hair and beard, the folds in the robe, &c., being most carefully cut. The whole bears a close resemblance to the minute work of the cylinder seals. Before the shrine we see Nabu-bal-iddina, the King, Nabu-suma-iddina the sculptor,—and one of the priests of the temple engaged in the worship of the solar disk.

The discoveries which have resulted from the slight explorations conducted by Mr. Rassam at Abboo Hubba have restored to us sufficient remains to show that the Chaldeans of the tenth century before the Christian era had distinct styles of art and architecture of their own, and that beneath the grave mounds of the Chaldean plain remains of their work exist, and it is to be hoped that further explorations will bring to light many more examples of the art of Babylonia, and thus restore to us the earliest chapters of the art history of Western Asia.

YRIARTE'S "FLORENCE."

The beautiful work on Venice, which M. Yriarte brought out some time since, and which we noticed fully at the time, has now a companion in the same author's newly published work on "Florence."* After Rome, these two cities stand without rivals in Italy in their historic and artistic interest. Neither of them, of course, comes near to the interest and importance of the "eternal city" in these respects; but Rome is a world in itself, and stands, in its endless variety of objects and associations, out of the category of cities which can be treated of in a monograph. Under her, however, Venice and Florence divide the prime interest of Italy; and it is curious how appropriately the two seem to stand in contrast and complement to one another. Venice represents Italian life impregnated with Oriental ideas and feeling; Florence is essentially a city of the Western world. Venice is the city of romance, of colour, of picturesque effect; Florence is the city of calm discriminating culture, of art flourishing under a *régime* of sound sense and clear æsthetic perception. The very architecture of the two cities carries out and illustrates the contrast. The prevalent character of Venetian architecture is romantic; it ignores rules and follows the dictates of a rich and exuberant fancy. The architecture of Florence is refined, grandiose, practical; but, in comparison with that of Venice, somewhat cold and formal. Take the Pitti Palace as the type of Florence, and the Doge's Palace as that of Venice, and we seem to have in those buildings not inapt external illustrations of the respective character and associations of the two cities. The contrast between the cathedrals of the two cities is less significant, inasmuch as the style of "St. Mary of the Flowers" is, in fact, much less Florentine than that of most of the principal buildings of the city, architecturally considered, though the history of the dome and of the practical knowledge and readiness displayed by its architect is characteristic of Florence; and we may feel sure that if there had been a Brunelleschi in Venice when St. Mark's was built, the building would not have been left in danger of slipping into the water off its foundations. But the domestic and palatial architecture of the two cities is the most significant of their character. The Florentine architecture, in its most typical form, is somewhat cold and deficient in picturesque elements; but in its aspect it seems to boast of such a completeness and logical suitability of design, such a stateliness and largeness of style, that it can afford to dispense with the mere prettinesses of picturesque variety. And this cold and rather self-satisfied æsthetic correctness was the intellectual character also of Florence in her great days. Her literature was a revived classicism, studied, correct, but somewhat cold and occasionally pedantic; her politicians were wary, cold-blooded, and crafty. Through the whole Florentine ideal of life there ran the predominance of intellect over mere sentiment. This is illustrated in the very countenances of the eminent men of the great days of Florence; and as we turn over M. Yriarte's profusely-illustrated pages and glance at the numerous portraits interspersed through them, we are reminded of the words of the Florentine "commissary of the Republic" in Browning's "Luria," who explained to his hearers that Florence had nothing to do with individual interests and fancies:—

> "Florence exists because these pass away;
> She's a contrivance to supply a type
> Of man, which men's deficiencies refuse."

This classification applies, however, more decidedly to the politicians, poets, and *dilettanti* of Florence than to the artists. If her poetry and her architecture were somewhat coldly correct and *rangés*, there were among her painters and sculptors fiery souls who broke through the Florentine ideal of sweetness and light, and became beacons for all time; but these men were hardly representatives of Florentine character and Florentine art, they were above it. Indeed, the same might be said of her greatest men generally. The three greatest names in connexion with Florence are indisputably Dante, Savonarola, and Michel-angelo, and they were all at bitter war with Florence, and, as regarded her society, they were *hommes incompris*. In this, again, how different from the case of Venice, where the greatest names in her art, Titian and Giorgione, were Venetian to the backbone.

In giving his birdseye view of Florence, M. Yriarte devotes an introduction to some general considerations, the place of Florence in the modern world, the art of Florence separately considered; then we have a summary of the general history of the city, followed by a much larger and fuller chapter devoted to the history of the Medici; the further distribution of the work is into chapters on "The Renaissance," on "Illustrious Florentines," on "Etruscan Art" (viewed as the parent of Florentine art, we presume, but this seems rather far-fetched), and on the public monuments, the sculpture, and the paintings of Florence. The introductory chapter may be briefly dismissed, merely noticing that the author regards Florence as in a sense the school from which the modern mind has learned, and in fact appears to take very much the same view which we have above expressed as to the especial correctness, refinement, and completeness characteristic of the Florentine ideal. She is, he admits, less grand than Rome, less strange, rare, and picturesque than Venice, but she has the pervading charm of culture and intellectual refinement in their highest and rarest form. To use the author's own words, — "Aujourd'hui encore, le marbre, le fresque, le manuscrit élaborés à celle époque fortunée, à Florence ou par un Florentin, portent un cachet unique et rare, quelquechose d'indéfinissable qui est fait de distinction suprême, de noblesse, de grandeur, de calme, de force et d'élégance discrète et contenue." Florence, in fact, is the only name which it is at all possible to group with that of Athens, the only city which can have any claim to be named in the same breath with Athens as the parent of æsthetic culture.

According to M. Yriarte's way of putting it, Florence is, in fact, artistically a descendant of Athens, in the sense that the characteristics of her art are those of Greek art revived. This is a theory which must be taken *cum grano*. In architecture, at all events, Florence is not the equal of, nor in the same category with, Athens, any more than any other city has been. There is to be found nowhere that intellectually perfected detail which distinguishes the Greek columnar style. Such a building as the Pitti is the nearest which she has to show to Greek architecture in regard to logical completeness in every part; but the style of the Pitti is, as every one must admit, a very coarse one compared with even inferior Greek architecture. In the Duomo and the Campanile, the latter especially, there is much more of grace and beauty, but here in turn the defect lies in the unsatisfactory treatment of detail. The style is one combined from the Gothic and Classic elements, which the Florentine architects, however, were not able properly to join into one; and throughout all the details even of the Campanile (which is superior work to most of the Duomo) we are continually conscious of an uncertainty of style, and even occasionally a feeling that the architect is trying to use details which he does not fully know what to do with. This is apparent, for example, in the tracery in the windows of the Campanile, which has the general appearance of a quasi-Gothic tracery, but when examined in detail is found to be clumsily put together, with some confusion as to plases and mitres, quite unlike the complete and finished way in which true Gothic tracery in the best form is worked out; and throughout the Campanile and the Duomo there is a clashing of Gothic and Classic feeling (leaving out of the consideration the dome, where we naturally expect this) which detracts very much from our satisfaction with the architecture from a critical point of view; not to speak of the radically unsatisfactory effect of a veneered architecture on a great scale, which has been often commented upon. When, however, we consider the Florentine sculpture, there is more obvious ground for the idea which connects it historically with Greek art. There is about the great works of Florentine sculpture a certain simplicity, reticence, and (to a certain degree) of stiffness of style, which strongly recalls Greek art of a slightly archaic stamp, and it is here, perhaps, that the view suggested by M. Yriarte becomes plausible or probable.

Tuscany was, as he observes, a region peculiarly privileged, centuries before the efflorescence of Florentine art. Etruria had an art of her own, remarkable for its naïve and realistic character, as far as its authors' technical abilities served them; and when Etruria became subject to Greece, it is natural to suppose that Greek art would have had a kind of new or special form of existence there, arising from the impression made by Greek genius upon native Etruscan art. Something of the simplicity and severity of the latter element would be retained, while the Greek element would give a new impulse and power to the native art. M. Yriarte engraves two bronze works from the Uffizii Museum, one the well-known chimera, the resemblance of which to archaic Greek is remarkable; the other a less popularly known bronze of an orator in the act of speaking, with outstretched hand. In this latter figure there is certainly much that is suggestive of early Florentine sculpture, in its simplicity of design and style, earnestness of expression, and even in the somewhat incorrect proportions and modelling. M. Yriarte draws attention to this coincidence in taste and style, without attempting to deduce any direct conclusions from the circumstances. He leaves it to another, he says, to investigate whether, between that art which died 280 years before Christ, and that which arose in Florence fifteen centuries afterwards, there was any secret analogy; whether the Florentine genius of Donatello was really the genius of old Etruscan sculpture, purified by a new civilisation. There is certainly enough artistic relation between the two,—whether accidental or not,—to be worth remarking upon. But with Rome coming in between, it seems to us that Etruria must have been pretty well eliminated. Certain Etruscan forms influenced Roman architecture, of course, notably; but, as to sculpture, we should take it as a matter of course that every trace of Etruscan *naïveté* had disappeared in the sculpture of the empire, which had assumed a character altogether its own,—the art of a wealthy and lavish society where there was no earnestness or simplicity left,—where all was show and ostentation. Roman sculpture only resumed something of this *naïveté* when it began to decline in execution, and it then may be said to have approached the Etruscan character again in a sense, but only inasmuch as it fell into a kind of second childhood, and showed some of the same weakness of execution which belongs to a half-formed as well as to a decaying art. It is with this late Roman sculpture that M. Yriarte thinks early Florentine sculpture is directly connected, especially

a

* Florence. L'Histoire—Les Médicis—Les Humanistes—Les Lettres—Les Arts. Orné de 500 Gravures et Planches. Deuxième Edition. Par Charles Yriarte. Paris: J. Rothschild, 13, Rue de Saints Pères. 1881.

through a certain class of sculptures,—those on the Sarcophagi; and he compares a Roman sarcophagus of the epoch of the empire with an antique sarcophagus now in the Ricardi palace, and formerly belonging to the Medici family, and of Christian workmanship. The bas-reliefs on the latter may be said to stand very well as a connecting-link between the work of the empire on the one hand, and that of Early Florence on the other hand. These ancient Christian sarcophagi, being carefully preserved as the memorials, and in fact, in a sense, the coffins of ancestors, remain also as models and suggestions at the revival of sculpture.

"The Campo Santo at Pisa shows us, under its spacious portico, sarcophagi which date from the epoch when Pisa counted among the important colonies of imperial Rome; the others have been transported from the East, or from Sicily and Calabria, and they date from the Middle Ages. In the eleventh and twelfth centuries, when the Pisans built the dome and that leaning tower which attracts travellers to Pisa from all the world, they took to decorate the exterior of the basilica those beautiful sarcophagi, of which the sculptures, which they were still unable to reproduce, struck them most. If, then, some great personage died, they found no tomb more worthy of him than that stone sculptured by ancestral hands. The Countess Beatrice, mother of the famous Countess Mathilde, and the Pope Gregory VIII., who died at Pisa in 1187, repose in such antique tombs. Charlemagne himself has for his tomb a Roman sarcophagus representing the burial of Proserpine; St. Andreol occupies the place where once reposed the remains of Tiberius Julius Valerianus, whose ashes have been scattered to the winds by Barbarian hands. The sarcophagus is, then, the link that binds together the past and the present; it is the instrument of the regeneration of sculpture; and when a man of genius shall stand meditating before the subjects which adorn the sarcophagi and compare the movement, the life, and the anatomical knowledge of the ancient sculptors with those of the stone-cutters employed in the construction of the dome, by a supreme effort he will endeavour to shake off the yoke of the Byzantines, the archaic stiffness and regulation order of the early Christian artists, who confine themselves to the production of symbols rather than sculpture, and he will have the glory of having freed Italian art and founded the school which will have regenerated the world of art." And this "coming man" is Nicolo Pisano, who "will play in sculpture the same part which Giotto played in painting and Dante in literature in Italy. And Pisano is a Tuscan born, so that the art born in Etruria is born again in a town of Pelasgic inhabitants a few leagues from Florence and from the Fiesole of the Etruscans." This, if a little fanciful, is not too much so to be reasonable also, and is at least very brilliantly put.

Sculpture is the only great Florentine art in regard to which this question of relationship with the past can afford much ground for discussion. Painting had no past to refer to; and the genealogy of Florentine architecture, mixed as it is, is obvious enough. There are two other historical chapters in connexion with Florence, however. There is the history of Florence herself, and there is the history of the remarkable family of merchant princes who are so intimately connected with her greatness, and to whom, indeed, M. Yriarte devotes far more space than he does to the history of the city itself. This disproportion, as it seems at first sight, may be explained and justified on the ground that the author's work is intended to treat of Florence mainly as she appears to the artistic eye, and in this light the influence of the Medici is of the highest importance. Touching, however, on the history of the city, M. Yriarte refers to the various theories about her origin, the most generally supported view being that Florence is Etruscan, or, at least, that she has partly arisen from the *débris* of the last Etruscan cities subjugated by the Romans. Machiavel makes Florence a Roman colony founded by some of Sylla's legions; but in the days of Machiavel history did not aim at scientific exactness, and to regard a theory as probable would have been sufficient reason to publish it as ascertained fact. Modern science, says the author, has persisted in seeing in the new city on the banks of the Arno the result of emigration from the heights of Fiesole:—"Fiesole, si belle sur sa haute colline d'où on suit le cour de l'Arno en comptant un à un les dômes superbes et les hauts campaniles de la ville des fleurs aussi séduisante par son aspect qu'elle est attachante par son histoire." M. Yriarte hardly lets us understand which theory he himself favours, unless he identifies himself with "modern science." It may be observed that the Fiesole theory, on the face of it, goes to justify Mr. Ruskin's somewhat fanciful title of his work on principles and axioms in art, "The Laws of Fiesole"; though, after all, it does not follow, because Florence emerged, materially speaking, out of Fiesole, that she drew her artistic life thence.

The lily is the proper emblem of Florence, but the arms of the Republic were continually being modified with each leading event in her history; events which we must pass over for the most part, and which are only briefly alluded to by our author. It was in the twelfth century that Florence, Pisa, Sienna, Arezzo, and Pistoia, constituted themselves republics. In the early part of her history, Florence was a kind of vantage-ground for the battle of the two celebrated factions, to become famous as Guelphs and Ghibellines, with the German Emperor pulling the wires, at the commencement of the feud at least, which, however, after that seemed to have no difficulty in keeping itself going, by the pure and unadulterated hate of the two parties, up to about the beginning of the fourteenth century. And when Guelphs and Ghibellines had had enough of it, but a brief period of repose elapsed before intestine fights were again set on foot for an indefinite period, between two fresh factions, the Neri and Bianchi. A very turbulent cradle for art it seems; and yet, as in some other instances, a strong healthy art took root and grew up there, in the midst of all this civil brawl and jealousy, prepared to blossom when the sunshine came. Towards the latter part of the fourteenth century the battle-cry had changed, though the fighting went on all the same; and now the rivalry was between Aristocrats and Populars. Towards the end of the century the Populars had the upper hand; but, in spite of their name, out of them grew up a new aristocracy. Eminent men among them amassed money, became bankers, and acquired great influence by their wealth. But among these, in the first years of the fifteenth century, "we see one family, that of the Medici, assume by little and little an almost incredible influence over the masses, and Giovanni dei Bichi, who was their chief, was named Gonfaloniere. The rejoicing at this occasion among the people was so great, that some of the men most attached to popular government, seeing this enthusiasm, foresaw that the Florentine people were ready to give up their power into the hands of a master. From that day, if one wishes to write the history of Florence, it is sufficient to write the history of the Medici." Florence had, in fact, passed through the natural and often-repeated progress from popular government, if not to despotism, at least to aristocratic government; for there could hardly be more thorough aristocrats, in all the essentials of the character, its good and its evil, than the leading men of the Medici family, in spite of their commercial origin and profession.

We refer the reader to M. Yriarte's pages for the history of the family, given at considerable length and with the added interest of a number of portraits and other illustrations. Our interest is mainly with that member of the family who became so remarkable an influence in the patronage and promotion of Florentine art and culture in the greatest days of the Republic. It would probably be a mistake to regard the Medici as in any high moral sense patriots or benefactors. Their strength lay in the fact that, as our author observes, having acquired enormous wealth, they used it in so intelligent a manner that their success became, in the natural course of things, the benefit of those who surrounded them as well as of themselves. There can be little doubt that from the first they thoroughly enjoyed the possession of power, and studied their own aggrandisement, but they were wise enough to see that they could do this in no surer way than by linking themselves with the success of Florence and Florentine interests at large, and rendering themselves necessary to these ends. Lorenzo himself, who is, as every one knows, the culminating figure in this line of banking princes, was, in his private character essentially a selfish epicurean, though in a grand and superb manner, which gives him a dignity even when considered in that light only. But he had the power of passing at will from the character of *dilettante* and man of pleasure to that of statesman and ruler; and being a man of great natural talents and splendid culture, his very pleasure lay in turning his wealth to the promotion of everything that could tend to stimulate the artistic culture of the day in the brilliant state over which he was practically ruler. That he was a man much loved or very loveable may be doubted, were it only on the evidence of that countenance, as familiar to all students of artistic history as that of Michelangelo himself. It is the face of a shrewd, self-contained, cynical man, gifted with acute critical perception; and that he was renowned for his ironical and biting repartees is what his very profile almost tells us without words. He was the centre of a life of æstheticism compared with which the æstheticism which is playing its part in modern society is but a child's game. His amusements took the form of fêtes and shows, in which all the artistic genius of the day that was within reach was drawn together to furnish designs and scenic effects, and a mine of wealth was squandered on giving pomp and splendour to pageants of a day. It is necessary to bear in mind this element to realise the part he played in the daily life of Florence, and perhaps to understand the general popularity enjoyed by a character not such as generally makes a man a popular idol. He amused the people in a most magnificent fashion, and that in itself was enough to ensure popularity. Of his more serious patronage of artists there is no need to speak; but it is not always remembered by those who connect his name with Michelangelo and the other great artists whose rising genius he fostered and encouraged, that he showed the same energy and the same breadth of view in his encouragement of literature and his formation of the great library which still bears his name. The world of which he was the centre was not a world of high moral tone; indeed, it may be said that the moral element was almost conspicuous by its absence, and artistic greatness was practically regarded as the main end of life and as synonymous with virtue. This was the characteristic of the age, which displayed in fact a grand reaction against the ascetic ideal of the Mediæval period; and the typical man of the day naturally represents this purely æsthetic ideal of life emphatically. But there was never any example of the exercise of great sway and the realisation of a magnificent and sumptuous mode of life, carried out in so dignified and intellectual a spirit and with such entire freedom from vulgarity. Florence under Lorenzo represents the highest point to which the purely æsthetic theory of life has been carried in practice.

In another article (for we have only touched on a few leading points in M. Yriarte's able work) we will draw attention to some of the lights thrown by the author upon the architecture and other arts of the great period of Florence. In the present number * we are enabled to give two of the illustrations from the work, the view of the Pitti Palace and that of the chapel containing the tombs of some of the last of the Medici. Concerning this chapel and the tombs it contains, M. Yriarte makes a significant bit of criticism. Lorenzo had been commemorated by a tomb, far from gorgeous in its scale or its decorative effect, but to which the greatest Italian mind of the day had given some of his greatest thoughts in sculpture, and of which it may indeed be said without hyperbole, that,—

"Kings for such a tomb might wish to die."

But these later members of the family came in a day when the great lights of art were themselves quenched in the tomb, and their remains repose in a chapel rich indeed with mere decoration, but which, in comparison with Lorenzo's monument, only serves to remind us what a gewgaw is mere decorative detail when placed in competition with the thoughts in stone of a Michelangelo.

The Committee of the Cabmen's Shelter Fund have had an architect's competition for an improved cabmen's shelter design. There were thirty-five entries coming from all parts of the country. The committee have ultimately awarded the premium of 10*l.* to Messrs. Harvey & Clarke, of London; and one of these new shelters will shortly be placed at the York and Albany cab-stand, Regent's Park.

THE NEW EGYPTIAN ROOMS AT THE BRITISH MUSEUM.*

Resuming our notice of the new arrangements, cases 31-33 contain a collection of flint flakes, and, what is more interesting to the artist, a very fine collection of so-called spoons, and boxes used by the ancient Egyptians for holding different articles of the wardrobe, toilet, and kitchen. These are made of various convenient materials, as wood, reeds, palm-fibre, papyrus, and ivory. Many of these are of very beautiful make, and the artist of Egypt 3,000 years ago was as clever in adapting elegant devices and designs to the exigencies of his work as the German wood-carver and the Austrian toymaker is to-day. Animal forms of great beauty, human figures with slender limbs and a peculiarly-graceful proportion of purely native conception, plants, flowers, fish, serpents, deities, and many other natural or imaginary objects have been thus reproduced by the carver to form boxes, spoons or scoops, and ornamental receptacles for treasured objects. The next cases contain baskets of elaborate construction, toys, musical instruments, specimens of linen, and tools. The tools and utensils used in ancient Egypt consisted principally of wood and bronze; iron, as we have already said, being rarely found in the sepulchres. Hammers of stone have indeed been found near the mines of Wady Magarah, but no date can be yet assigned to them, and it has been conjectured, but without positive proof, that the Egyptians set flint flakes in handles, and used them as chisels and scrapers to carve calcareous stone, steatites, and other soft materials. A large variety of tools have, however, been recovered, but they are of a primitive and almost puerile form; such as bronze chisels, wooden mallets, bronze saws, adzes, drills, awls, and other such implements, of some of which the use is unknown. The plasterer used an adze, and spud or trowel to lay the plaster on clay walls toughened with straw, and covered his work with distemper or whitewash which was laid on with a coarse brush of palm-fibre. Wooden materials were covered with coarse cloths glued to them, and then treated to a heavy body of white colour laid on thickly and smoothed over. Upon this the paintings were executed. The invention of music has been ascribed, by many other nations as well as the Egyptians, to the gods. Here Thoth, the Hermes of the Nile, invents the lyre; Neith, the Minerva, invents the flute; and Bes, a kind of grotesque infant Hercules, clad in lion's hide, performs upon the trigon or triangular harp; while the sistrum or metallic rattle is the favourite accompaniment of Athor and Isis. The forms of musical instruments shown on tomb walls are various. They comprise the harp, carrying from four to as many as twenty-two strings (one tomb is known as Bruce's or the harper's tomb from the elaborate harps depicted in colours on the walls), lutes, lyres, guitars, drums, flutes, and double-flutes, trumpets, sistra, clanking chains, cymbals, and castanets. One of the stringed instruments in the British Museum is a wooden harp or guitar of peculiar shape, borne on the shoulder when played, and having four cords when perfect. It is covered with parchment, and has a bridge and a portion of one catgut-string remaining. This curious instrument comes from Thebes, a site fertile in the finest relics of ancient Egyptian art. Among the toys are several draughtsmen of interesting form, some inscribed with royal names; wooden and bronze dolls with jointed limbs; balls of white or scarlet leather stuffed with chaff, birds, crocodiles with moving legs, little models, and vases. The linen stuffs which are in this set of cases are entirely of flax, no cotton having been used, but woollen fabrics ornamented with embroidered patterns have been occasionally found in tombs. Some of these are fine, others coarse as canvas. The flax-stuffs were generally made in long narrow strips, and their uses were various, as dress, armour, mummy-shrouds, and coverings. The selvages of some have been found to be dyed with indigo, and old linen, when discoloured, appears to have been dyed red with the *carthamus tinctorius*. Bronze needles, threads, spindles, and reels have also been found. Among the specimens exhibited in this class is the linen shroud of a mummy, inscribed with the name of king Piankhi, a monarch of the twenty-fifth dynasty, which has been dated from B.C. 715 to 666.

The two upright cases between the windows in this room contain furniture, pillows or head-rests, chairs, and miscellaneous objects; and the cases in the middle of the floor-space are filled with a large collection of objects of attire and personal adornment,—wigs, dresses, glass, inscribed and painted tablets, inscribed and engraved stones, shoes, sandals, beads, necklaces, and pendants; bracelets, boxes for holding stibium and cosmetics, rings, inlaid tiles from Tel-el-Yahoudeh and other sites, blue porcelain articles, and the necessary paraphernalia which go so far to make up the conventional amenities of domestic life. In the drawers of some of these cases are stored up a number of papyri in continuation of those which have long been exhibited on the walls of the staircase leading to those rooms. The space at command on this occasion will not allow of a detailed description of these objects. The draughtsmen, however, deserve a passing mention. Among the ancient Egyptians there were two games played in some respects like the modern draughts or "fox-and-geese" games. They used a board divided into thirty squares, three one way by ten the other way, and another form which had twenty squares, twelve of which were arranged three one way and four the other, while from the middle of the smaller side eight squares stood out in a line. The two players had five or six pieces each, generally conical or sugar-loaf shaped; of the relative values and moves of the respective pieces little is known. There was also another game of "*robbers*" or "*latrunculi*," some men of the sets used in it being in the British Museum collection. Another game, of which little is recorded, is that called *han*, or the "*vase*," played with movable men upon a series of concentric lines marked on a circular board. One of the draughtsmen exhibited in this department is reputed to belong to the extremely remote period of the fourth dynasty, the beginning of which Mariette dates at B.C. 5004, Lepsius at B.C. 3892, and Wilkinson at B.C. 2700.

The papyri, apart from their manifest literary and historical value, are of considerable importance on account of the early forms of pictorial treatment which they enshrine. These very ancient relics of native African art are totally distinct from all other Oriental illuminations, and in some of their later peculiarities affected, and were affected by, the so-called Byzantine spirit that breathes more or less in all the earliest remains of human handiwork which is not pre-historic. We are told, in Birch and Jenner's Handbook to the Illuminations in the British Museum, that although some of the Egyptian illustrated papyri are as old as the fourth and fifth dynasties, written in the hieratic character, the use of vignettes or pictures does not appear to be earlier than the eighteenth dynasty, which existed from about fifteen to seventeen hundred years before our era. Then the figures are of moderate dimensions, traced in outline, the hair and other details black. At this early period colours were, however, freely used; blue for water, green for plants, yellow and red for details, and some vignettes were even gilded. Another style was to draw the outline only and leave the picture uncoloured. But so dominant was the principle of illumination at a remote period that the text of the papyrus is occasionally sacrificed to afford sufficient space for the insertion of the pictures. The colours were laid on in tempera; the black being an animal charcoal, the red an ochre, the blues and greens derived from copper, the white a fine chalk or gypsum. These were laid on flat or in monochrome, either without shading or with very faint and undefined attempts, and a strong black outline surrounds all the figure. These vignettes are not varnished. One of the most magnificently illuminated rituals of the nineteenth dynasty is that known as the "Clot-Bey" papyrus of Hu-Nefer, keeper of the oxen of king Seti I., considered to be the finest extant. The date of this is about B.C. 1200. After the nineteenth dynasty, which terminated in the thirteenth century B.C., comes the great historical papyrus of Rameses III., called the "Harris" papyrus in honour of its finder, the Egyptian traveller, which was published by Dr. Samuel Birch, under direction of the trustees of the British Museum in 1876; this is splendidly illuminated. It contains three large vignettes with figures of considerable size; the flesh of the monarch and of some of the figures is coloured white. After this period, although brilliant colouring is still employed, the drawings become faulty in proportion, and depart from the Egyptian canon of art. The practice of illumination in colours was continued to the twenty-sixth dynasty, but at that time outline was almost if not exclusively preferred, and some of the vignettes are drawn with a remarkable fineness and sureness of hand. Under the Roman rule, illuminations are found on papyri in which a scarlet or minium appears to take the place of the usual red ochre; light greens and pinks are extensively affected, but the later papyri of the Roman period are only illustrated by figures badly drawn in black outline. Besides the Clot-Bey and Harris papyri already mentioned, there are several fine ones in the Barker, Hay, Wilkinson, Sams, and Salt collections. That known as "Kelashar" is a magnificent hieratic of the Roman period with pink, green, red, and greenish yellow colours.

The second room is dedicated to the reliques of the dead. Cases 1-11 contain fragments of richly-gilded and ornamental mummy-cases and paraphernalia of the departed. Cases 12-21, a series of the finest mummy-coffins, set up erect, and now placed on revolving pivots, which enable the student to examine the elaborate ornamentation of all sides of the coffins. Above these, against the wall of the room, are a number of less pretentious, but not less ancient and interesting, coffins, constructed of thick slabs of wood of a dark colour, hewn and shaped with artistic care at a great labour considering the nature of the material and the poorness of the tools at command of the artificers. The middle of this room receives the mummies which formerly occupied a corresponding position in the old room. These were prepared with salt, bitumen, cedar oil, and other substances to resist decay, corruption, and the ravages of time. Notwithstanding this, the descent into a mummy pit has been described by those few who, like Harris, ventured down into the Cimmerian darkness and groped about among putrid remains rendered more hideous still by the confusion which the Arabs had made in vain search for treasures, as an appalling adventure. Harris himself was rewarded by finding a valuable papyrus in the clenched hand of its desiccated author, and another hidden in the semiliquid bitumen which filled the abdomen of another mummy. This preservative process was thought to enable the soul to return to its body after a course of transformations, which occupied from 3,000 to 10,000 years. Dr. Birch, in his description of the Egyptian collections, gives several details of the manner in which the preparation was effected. Silver gloves or finger-stalls were placed on the hand to preserve the position of the nails, and at the end of the process the body was wrapped in linen bandages, principally strips of 3 in. or 4 in. wide, several yards in length, laid on wet, remnants of old linen being frequently used for the purpose. As many as 700 yards are said to have been employed for a single mummy. Over this came a network of blue porcelain bugles, figures of sepulchral deities, scarabæi inscribed with mystical words and phrases, and a variety of emblems, of all of which the British Museum possesses in these rooms an immense collection. A very common mode of ornamenting the mummy was with a *cartonnage* composed of from twenty to forty layers of linen tightly pressed and glued together like pasteboard, then covered with stucco, and gilded. Of this, several examples are exhibited. Among the many instructive objects shown in these cases is the mummy of a little girl, in a coffin and bandages. The coffin consists of a flat board with vaulted cover, on which is the figure of a sacred snake. On the outer wrapper or shroud of the mummy is a painting of the deceased child, full-faced, wearing a wreath, a long white garment, and sandals. It is attributed to the Roman period. The peculiar tenderness with which the picture has been designed, the full, imploring eyes, the head leaning to one side, and the wistful expression of the countenance of the little child, attracts the attention at once in a forcible and affecting way. We can readily imagine the feelings of the parents of 2,000 years gone by who could find a solace under their loss in the contemplation of this relic. Near to this are the remains of the cedar coffin of Ra-men-ka, or Mycerinus, a king of the fourth dynasty (according to Mariette, B.C. 4235; Lepsius, B.C. 3122; and Wilkinson, B.C. 2450), found in an upper chamber of the third pyramid at Gizeh during excavations made by the late General Howard Vyse; the coffin of Enentef, a king of the eleventh dynasty (*i.e.* nearly 5,000 years ago), painted and gilded, from Thebes; and the mummy of a priestess, named

* See p. 441, *ante*.

Katb, in a sycamore coffin painted buff-colour. The mummy, which is still enwrapped in its proper bandages, has part of a *cartonnage* representing the face and features, gilded with a pale-coloured gold or electrum, alabaster earrings, and a collar of beads. The hands are of wood, crossed, with bracelets representing symbolic eyes in gold and tin. On the fingers are rings, and on the breast a pectoral plate of metal, with a scarabæus in form of the goddess Nut, and a sepulchral figure. The hair of this priestess, which was embalmed separately, is laid at the side of the head.

Passing over many important objects in these divisions, the next cases, Nos. 22-27, are devoted to the reception of mummies of animals; among them may be noticed cynocephalus apes, dogs, jackals, cats, kittens, bulls, rams, gazelles, hawks, ibises, snakes, eels, and fish. The animals employed and maintained by the sacerdotal class for the purposes of divination and veneration, and perhaps we may add of mystification, were especially subjects for mummification after death. Perhaps favourite household pets were also so distinguished. Next in order come the sepulchral tablets and boxes, followed by the large series of sepulchral figures of the Osirian or beatified dead, in cases 28-38. These figures, for the most part blue or pale lavender coloured porcelain, highly glazed, a few in ebony and other wood, copper, stone, and clay, are called "Shabti," or "Ushabti," that is "Respondents," or "coming when called." They commence with the reign of Amenophis III., a king of the eighteenth dynasty; they are in shape of a mummy, inscribed with an early text of the chapter or formula of ritual, not found on later figures. Later on, the sixth chapter of the Book of the Dead is found cut or inscribed upon them. After the time of the twenty-fifth dynasty (about 700 years before the Christian era), and during the twenty-sixth (which existed from B.C. 666 to 526), the figures take the shape of a small statuette, having the body mummied, the hands holding the hoe and pick-axe, and cord of the basket,—all emblems of Osiris by whom the deceased was justified and prefigured. They had also a small pedestal at the feet, and along the back an upright plinth or pilaster from neck to heel. The inscriptions record the name of the deceased person in whose tomb or coffin they were deposited, preceded by the term, "The luminous Osirian." An excellent account of these figures and an interpretation of the mystical chapter they carry on them may be read in the "Zeitschrift für Ægyptische Sprache," 1864, pp. 89, 103, and 1865, pp. 4-20. Several hundreds were frequently placed in one tomb, and as they then are of different fabrics, apparently made by different manufacturers, occasionally the space for the name of the dead person is left blank in the inscription.

Cases 39-44 contain a large series of sepulchral cones, and a set of wooden figures of the triple god, Ptah-Socharis-Osiris, the demiurgos of the kosmos, or universe. Some of these have hollowed interiors, adapted to hold parts of mummies, or rolls of papyri. Nos. 45-48 contain Græco-Egyptian and Roman antiquities from Egypt; and the concluding cases 45-48 sepulchral vases, chests, and miscellaneous antiquities found in tombs and sepulchres. The sepulchral tablets contribute much that is known about all branches of the Egyptian religion, history, and civil life, ranging from the ancestral worship which prevailed of the early dynasties to the later adoration of the deities of Hades. The types of deities are furnished by these tablets, and the sacrificial objects offered upon the tables show the things alone allowed to be presented to the divinities. In them, too, we see the modes of adoration, by standing or kneeling, the attitudes of subordinate members of the family, the titles enjoyed and the offices held by the deceased, their names, parentage, and social position; the feats of arms and personal prowess of individuals recorded herein, often render contributions to the somewhat scanty materials of history which have survived the wreck of ages. For in these two rooms, which we have hastily passed in review, we see stored up the remnant of a mighty race, in which for a time the whole of human progress was wrapped up. The destiny of the soul, and the condition of man in his future state, occupy, naturally enough, a large part of the representations of these tablets. The power of entering and quitting Hades, the accomplishment by the soul of its prescribed destiny, the welcome offered by the infernal deities to the liberated and purified spirit, are all shown here, and it is not until the late age of the Ptolemies, the decadence of pure Egyptian religion, that a dread condition is attributed to Hades, and a pessimistic view taken of the future condition of the soul.

As we look back to the remains of an age so remote as this which is displayed in these collections, the origin of modern civilisation can be traced in its primary development, and the germs of sciences which hurry us forward today can be found. "Philology," writes Dr. Birch, in a work about to be issued, "here can deal with a written language older than the remotest forms of Aryan speech; writing, with the first attempts to convert the elements of sound into a pictorial form. In arts and sciences the inventions of mechanical contrivances, tools, weapons, and the simpler machines, can be traced step by step. The loom, the plough, and press, are first seen at work. Painting, sculpture, and architecture appear in their earliest forms, while the arts of chemistry and mechanics evidently underlie them, as the principles of mathematics, abstract and mixed, are clearly involved in the eminence at which the productions arrived." The great length of antecedent time necessary for the experiences which lead to invention has also to be borne in mind as the discoveries had apparently to be made in Egypt itself, which, in its earliest period, does not appear to have received its civilisation from external sources, the arts of Asia being neither so old in point of time nor so excellent in regard to execution. Hence Egypt alone is the sole source from which all are derived, and in which the evidences of their derivation have most happily survived; and it is a paramount obligation with us to preserve with intelligent care, and to transmit without further dilapidation and deterioration to a posterity perhaps even more intellectual than ourselves, and therefore more keenly appreciative of the relics of human art-inception, these sacred heirlooms of the race of man upon the earth. Whether they will last for a length of time—the same as they have already survived under the exceptional circumstances from which they have been removed to those under which they are at present placed—is a matter of question. They have now to follow the vicissitudes of modern civilisation instead of the quiet peace of the underground tomb, or the safe hiding of the dry, warm, sand of their native land, and they have exchanged the clear air of Egypt for a humid climate adverse to the durability of the frailer materials of which they are in a great measure composed. Protected, then, by the very neglect they suffered,—unheeded and unsought for in the depths and corners of the darkling sepulchres,—they are now brought up into the outer world, and owe their preservation to the interest which attaches to them on account of their relation to the present state of historical research and philological science. But it will be a long time before we get beyond the lessons they impart, and the mysteries they still refuse to surrender.

WHAT SHOULD BE THE RELATIONS OF PAINTING AND SCULPTURE TO ARCHITECTURE?

On this subject the following paper, by Mr. H. Heathcote Statham, was read in the Art Department at the Social Science Congress:—

In endeavouring to suggest an answer to the above question, I have at least one advantage, viz., that I have not the slightest idea what those who proposed the question meant by it, or what direction they wished the consideration of the subject to take. Being thus entirely free to follow my own ideas in treating the subject, I may say at once that the question appears to me to be capable of consideration in three different lights. First, in regard to the definition and limitation of the profession of the architect; secondly, in regard to the place which painting and sculpture should take in the general architectural scheme of a building, and the degree in which they are or are not independent of the architecture; thirdly, in regard to the practical relations which should subsist between the architect on the one hand and the sculp or or the painter on the other, in the actual designing and carrying out of a building.

The first head, the definition of the profession of architect, is an important element in the discussion of the subject, for this reason, that it involves an answer to the question, whether the architect is to be regarded as directly responsible for the painted and sculptured decoration of the building; whether, in short, he is to be practically a painter and sculptor, or a designer of painting and sculpture; or whether he is to leave these adornments of the building to the hands of artists who have made a special study and profession of those branches of art. Upon this point there have been all kinds of contradictory opinions, architecture being at present not only the best-abused profession of the day (which is partly the fault of the architects and partly due to ignorance on the part of the public and of the leader-writers in the *Times*), but also the one about the nature and the duties of which the most vague ideas are entertained. According to one theory and practice, an architect is little more than a man of business, drawing plans, writing specifications, arranging the sale of house and land property, and conducting arbitrations. According to another view, he is an ethereal and all-gifted genius, having at his finger-ends every sort of artistic design, able to model sculpture and to furnish cartoons for frescoes, and equal to everything, except when sometimes his pure soul may be vexed by an awkward question about a drain. And between these two extremes is to be found every intermediate shade of idea as to the entity of an architect, most of them about as precise as that which was furnished to me one day by an engineer, of whom I asked in what he considered the difference lay between his practice and that of an architect, and who replied, "Oh, every one knows that; an architect is a man who draws houses and churches and things,"—the engineer, therefore, being, presumably, a man who "draws bridges and things." Yet there is really nothing vague in the matter at all. The province of the architect is capable of a perfectly simple and intelligible definition,—Architecture is the art of "building *with expression*," and the architect is the professor of that art. That includes all the practical and constructive part of building, as the basis, with the addition of picturesque effect or expression embodied in the arrangement of the plan of the building, the grouping and outline of the whole structure erected upon that plan, and, finally, the further expression given by the addition of ornamental detail and its characteristic design and treatment. When a man plans and builds a structure without any consideration at all for its appearance or expression, but only in regard to its practical utility, then he is purely an engineer; but, in fact, there ought not, rightly speaking, to be any essential distinction between architecture and engineering as far as buildings of any kind are concerned. A bridge ought to be as much a piece of architecture as a church, and is as much susceptible of architectural expression, and the distinction between an architect and an engineer should be regarded only as that between men occupied in different branches of the same profession, just as a Chancery barrister takes a different class of cases from a railway barrister, though both ranking in the same profession. As a matter of fact, a large proportion of the structures built by engineers are either destitute of architectural expression or are examples of architectural forms misapplied; but that fact does not affect the principle. Now, having defined the architect as a man concerned in building with expression, from the arrangement of the plan up to the ornamental detail, I should draw a line there and say that when you come to the addition of painting and sculpture a new form of art is introduced, and a new artist must be brought upon the scene. Architectural design and ornamental design (which is really the same class of art carried into minute details and emancipated to some extent from the trammels of construction) represent a form of art which does not directly imitate nature, and does not express definite ideas or raise definite emotions; it deals only with the general expression derived from order, repetition, symmetry, and balance of parts. Painting and sculpture do imitate nature, and do express definite ideas and excite definite emotions, and, therefore, belong to a different category among the arts, and require different genius, different studies and powers, from those which go to furnish the architectural artist. The idea that the same man may acquire and wield these various powers is quite futile, as all experience goes to show. There have been modern architects who have taken up the idea that they would design their own figure-sculpture for their churches and other buildings. I

should like to ask how much of the sculpture so designed would have had a chance of acceptance at the Royal Academy, where the standard of sculpture certainly is not extravagantly high? On the other hand, we have the case of such a man as Michelangelo, who is spoken of as an example of one who was painter, sculptor, and architect. He was a great genius, and in every way a most exceptional man; but the great architectural work usually credited to him is one of the worst-designed buildings in detail in the world; the dome was so badly constructed that it nearly came down again; and it is now proved by documentary evidence that all the good points in the general design of St. Peter's were due to Bramante, whose chief study was architecture, and whose design Michelangelo spoiled in carrying it out. Probably the only man in the history of art who had the faculty to be equally great as an architect and as a painter was Leonardo da Vinci, by whom there exist some architectural studies which look like the work of a man who had given his whole mind to architecture; but then Leonardo was the most exceptionally omniscient artist who ever lived. On the other hand, the idea which has been promulgated by Ruskin (whose architectural criticism is of an exceedingly *dilettante* character), that architecture is no art, and has no sufficient interest without sculpture and painting, need never be entertained by those who know how much matter for interest and study lies in the combination of practical construction and practical planning with architectural expression; how very much of art there is or should be even in the planning of a building; how very few modern buildings are artistically planned; and how large and varied is the field occupied by ornamental design as an art perfectly distinct from that of the sculptor and painter.

Having thus endeavoured to shew that the architect has quite enough to do without attempting to meddle with sculpture or painting, and that his own especial work, if properly and fully carried out, is sufficiently honourable and important in itself to rank as an art and to demand the best efforts even of men of exceptional ability, let us consider what is the relation which sculpture and painting should bear to architecture when brought into direct combination with it as contributing to the total effect, and whether these arts are fulfilling their highest function in contributing to heighten architectural effect, or whether, in their highest achievements, they demand to be considered separately, and for their own sake alone. To many critics, and some artists of the present day, the latter suggestion will seem absurd, and hardly worth consideration. There is at present a very general assumption, among people who write about art, that painting has lost much of its interest and life in the present day in part through the prevalence of easel pictures, and that if we only took to painting on the walls in fresco, there would at once be an immense revival of art. Why that should be I fail to see, and I have never found any one who could explain it satisfactorily. If there is a dearth of originality and power in modern painting, it is difficult to see how these qualities are to be developed by merely adopting a different medium of execution. The frescos executed by well-known painters on the walls of the Houses of Parliament are not superior in style or imaginative power to the oil-paintings by which they made their reputation. Sir Frederick Leighton's fresco at South Kensington is not his highest title to admiration. What would be gained by the general adoption of wall-painting as a decoration to our buildings is probably this, an increased demand for painting, and a consequently more extended scope for artists, and the opportunity of carrying out paintings on a larger scale than is usually practised in this country at present. But the idea that painting and sculpture necessarily gain by being connected with a scheme of architectural design, appears to me to be so far from the truth, that I would be disposed to say on the contrary that a work of the highest class, whether in painting or sculpture, demands an isolated position and undivided study; that it is rather lowered than raised by being made to play the part of an element in architectural decoration; and that painting and sculpture really cannot be brought into decorative combination with architecture unless they part with some of their own life, and are conventionalised so far as to harmonise with the severe and lifeless art of architecture.

If we take sculpture in particular, an art naturally more nearly allied to architecture than painting, we find that it is susceptible of almost every grade of conventionalism, down to a point at which it seems almost to blend into architecture. Egyptian art furnishes the most striking examples of this. In the avenues of sphinxes which formed the approach to their temples, figures all repeating the same fixed expressionless countenance, it would have been difficult to define whether the impression produced was architectural or sculptural. A single such figure would not have any particular interest or dignity except where colossal dimensions (as in the case of the sphinx *par excellence*) might impart these qualities; a long row of such objects is at once impressive, and hence we see that this form of sculpture is in reality to be regarded as a colossal architectural ornament. The caryatide figures introduced occasionally into Greek architecture are in some cases examples of a similar architectural use of sculpture in the repetition of somewhat conventional and expressionless figures, identical in treatment, and forming, in fact, not so much an ornament to, as an actual portion of, the architectural construction. And as long as sculpture is thus employed as a portion of the architecture, not as an arbitrary addition, it must be treated in this severe semi-mechanical style, or it will lose its unity with the architectural design, and appear to be crushed and overpowered by the architecture. In short, if you are to use sculptured figures as part of the architecture you must take the life out of them first, or they will protest against their usage. Even the celebrated figures in the porch of the Erechtheum are an instance of this; they would be models of architectural sculpture if they were placed in niches or otherwise framed in the architecture, but being made a part of the construction and carrying the roof on their heads, they always appear to me to be subjected to a menial office in the design which they are far too good for, and which in some degree degrades them. When we come to the question of sculpture which is framed in the architectural design, and not a part or an apparent part of the construction, the sculptor can have much more latitude. But even here, as long as his work is to be regarded as a part of the architectural design and to be considered in combination with it, it must be reduced to a certain conventionalism of character and repose of line, otherwise it will inevitably interfere with the repose and balance of the whole, and will assert its individual life too strongly. I will illustrate this by a reference to the front of Wells Cathedral, the most largely decorated with sculpture of all the English cathedrals. There are on this rich-looking architectural façade sculptures of two perfectly different types. The majority of the figures are large, above life size, and mostly formal and stiff in attitude and clad in full robes. Near the top of the façade, however, there runs across the building a series of niches filled by nude figures about half life size, in violent action, representing the Resurrection, the dead in the act of coming to life and rising from their tombs. They are different from any other sculpture in our Mediæval cathedrals, and were probably executed by foreign artists. Examined in detail they are very fine and pathetic, but are too high up to be seen properly from below, and, owing to their comparatively small scale, they have no effect on the general character of the façade, but might easily be passed over in a general survey. As sculpture, these figures, though much dilapidated, are superior to anything else on the façade; yet we may say, without a shadow of doubt, that if the figures which fill the greater part of the façade had been like these, had been figures in violent action and expressing violent emotion, the architectural effect of the whole would have been far inferior in dignity and grandeur to what it actually is. The figures would have disturbed everything and taken away all the repose which is essential to the highest architectural effect. The moral is, when you wish to use sculpture as an essential element in the total effect of a building, you do not require the most elaborated and life-like forms of sculpture; you must, so to speak, architecturalise the sculpture so as to make it harmonise with its position, and give a general expression and meaning to the building without too strongly obtruding its individual expression or character. When you do want to connect sculpture of the highest class with architectural effect, it is to be done not by making the sculpture part of the architecture, but by placing it in a commanding position in front of or in the midst of an architectural composition, which may serve as a worthy background to it, while the sculptural work stands out in the isolation which is required for its proper study and its full effect.

The question with regard to painting is less complicated than in the case of sculpture, because works in painting never can form, or appear to form, part of the architectural construction; they must always appear as decorative additions. But, with this exception, the same kind of conditions exist as in the case of sculpture and architecture. If the painting is to be what it is the fashion to call "monumental,"—to appear as an indestructible portion of the building, and closely allied with the architectural design, it must give up some of the realistic effect and emotional expression which belong to the painting that comes nearest to the representation of nature and of human life and character; it must avoid anything like scenic or perspective illusion, which would interfere with the solidity of the architectural effect, and it must represent figures and actions with that degree of conventionalism which will harmonise the picture with the repose of the architecture. The most highly-finished class of easel pictures painted in oil cannot thus be blended with architecture. Such pictures are in the nature of poems complete in themselves, with their own special life and interest, and which are, therefore, rightly treated as separate works to be framed off and studied each for its own individuality of interest. The only approach you can make towards assimilating such pictures with the architecture would be by spacing and dividing off the design of the walls into panels having a direct relation to the size of the pictures, so as to give to the room and the pictures the appearance of having been intended for each other,—an idea which it would be worth while to carry out when the object was to show some fine pictures in an effective manner; but in such an arrangement anything like an attempt to make the paintings seem part of the wall must be carefully avoided; they must appear as they are, separate objects. When the painting is executed on the wall and is to harmonise decoratively with the architecture, it will be found that, as with sculpture, exactly in proportion as you wish to make the painting a part of the architectural design, must you conventionalise it and throw it back from the plane of realism. In this respect there is no doubt that mosaic is the method which most completely combines with architecture; mosaic being in fact itself a kind of building on a minute scale, and having that solidity, hardness, and brilliancy of surface which gives it all the appearance of being part of the structure itself, and as durable as the building in which it is placed. Moreover, the brilliant effect of mosaic is peculiarly valuable where it is desired to have a richly-coloured interior decoration, as the picture in mosaic can then take its place as the strongest point, the high light in the decoration, to which everything else leads up; that being the position which decorative paintings always should occupy in a scheme of decoration; they should always be the culminating point. For this reason the less brilliant texture and usually lower tones of fresco render it less suitable for richly-decorated buildings; it comes in better where low tones of colour and a broad repose of effect are desired, and admits of more varied and realistic treatment than mosaic, though this licence must be carefully limited if the painting is to keep its place in the architectural scheme. The danger of approaching too nearly to purely pictorial treatment in such a case is illustrated in some of the frescoes in the Houses of Parliament, which are reproductions of oil paintings, and executed in as realistic a style as the material will admit of, producing an effect entirely at variance with the architectural framework in which they are placed. It may be observed, in connexion with this part of the subject, that Baron Triqueti's method of executing pictorial designs in inlaid marble had some peculiar advantages for architectural decoration, being capable of being executed almost in the same material as that in which the building was finished, and being, like mosaic, a picture architecturally built up and of indestructible materials; and it seems a pity that a better trial has not been given to this method of decorative painting, if so it may be called.

But whatever method may be employed in carrying out decorative sculpture and painting

in a building, two things are absolutely essential; first, that the subjects should be suitably chosen, and the paintings or sculptures should form a completely arranged series with a distinct point and meaning in the parts and the whole; and secondly, that the architecture should be, and should manifestly appear to be, specially designed for that particular series of painting or sculpture, and not built at haphazard to be turned over to the painter or sculptor to do what he can with it. And this brings us to the third point, what should be the relation of the architect to the painter and sculptor in actually carrying out the building. And here I would reinstate the architect. I proposed before to cut him off from any pretension to be a painter or sculptor; but I would place him as the directing mind of the whole scheme. It would be his province not only to plan and design the building, but to consider beforehand what decorative painting or sculpture he would have introduced in it, what ideas they should illustrate, what method or style of work should be selected, and then to provide for this in the architectural scheme, so that the whole should appear as one idea intended from the first, and deliberately carried out step by step. In such a case the architect may expect to have, and should have, some control over the work of the sculptor and painter; should be consulted by them, and should have at least a power of *veto* against any design which he considers opposed to the general effect aimed at in his building, and to the result which he planned from the first. It is only, however, where the architect has given this deliberate thought to the whole scheme that he can claim the right to control the painter and sculptor. If he has merely left a space for a painting here, and a niche for a statue there, without any consideration as to the subject or even as to the effective lighting of the work when *in situ*, the painter and sculptor may reasonably say, "You did not think of us, and we are not bound to think of you." That is not the way to produce a great and complete artistic result, but it is the way the thing generally is done; partly, because the architects will not take the trouble to think and plan out the whole scheme beforehand; partly because, if they were willing to do so, not one in a hundred of their employers would allow them the necessary time; the object usually being not to get as perfect a building as possible, but to get it finished at the earliest possible date.

This is what appears to me to be the truth in regard to the relation of sculpture and painting to architecture; and the practical deduction from such a conclusion would be this,—That those who are concerned in the erection of large buildings, especially public buildings, would do well to endeavour to combine decorative sculpture and painting with the architecture in order to increase the interest of the building in detail, and the richness and variety of the total effect; that to do this successfully requires that the whole scheme of the architecture and the decorative art should be considered and worked out as a whole by one directing mind, who should be the architect; and that to do this well necessitates much more time and deliberate thought than is at present generally bestowed or allowed for in such cases. That the more general employment of sculpture and one or another form of pictorial design in connexion with architecture would add much to the interest of our buildings, would afford many more opportunities than now exist to sculptors and painters, and would be likely to promote public taste for and interest in art by familiarising the popular mind with artistic design; but that it is a fallacy to expect that such a course would necessarily create or foster a higher standard of artistic genius in sculpture and painting, and that, on the contrary, the very highest works of genius in those arts must stand alone and on their own merits, and cannot be bent into subservience to an architectural scheme. The dilemma is similar to that in which the art of music is placed by the new school of lyric drama founded by Wagner. In that school the attempt has been made, with a great degree of success in some instances, to make the musical composition progress hand in hand with the dramatic action at every step; but this is done at the cost of curtailing and breaking up the development of the musical ideas in order to reduce them to obedience to the details of the dramatic action and story; the total effect is more logical, but the music is, in itself, much less interesting, and is almost unmeaning apart from the drama. Similarly, if we wish to bend painting and sculpture into decorative arts, forming part of an architectural whole, we can only do so by reducing their emotional expression and conventionalising their style and execution so as to fit them for their proper place in the general scheme of design, and thereby producing art which, like Wagner's music, will contribute to a logical whole, but will be of inferior interest apart from that connexion. To suppose, therefore, that such a system would lead to a quickening of artistic genius and invention in these arts seems to me to be a groundless, if not an absurd, expectation, and seems equivalent to saying, "The greatest artists of the cinquecento period painted in fresco on the walls of buildings; let us also paint in fresco on the walls, and we shall be sure to become great artists." The fact is that the reasons for the artistic greatness of one age and the artistic weakness of another lie much deeper than this; that they are, in fact, quite beyond analysis. Artistic inspiration and genius, like the wind, bloweth where it listeth, and we cannot say whence it cometh or whither it goeth. It is glowing and spontaneous in one age; it is cramped, stunted, and tentative in another. We may be conscious of and lament its decay, but we can really do no more; it is not at the beck and call of any theory, however complete and logical.

ARCHITECTURAL EDUCATION.

UNIVERSITY COLLEGE, LONDON.

The following is the opening lecture of the courses in Architecture and Construction at University College for 1881-82, delivered by Professor T. Roger Smith, on Monday evening last:—

It seems to me fitting that on this occasion, which forms the commencement of my duties as Professor of Architecture in this College, I should devote the opening lecture to an account of the course of instruction given in the architectural classes entrusted to me. In doing so I shall state what has hitherto been done, and what I purpose to attempt, in my conduct of the classes, I shall offer a few suggestions to students to show how they may best profit by the advantages which this college places within their reach; and I shall point out in what parts of their professional education the courses here given will assist them, and in what they must rely upon other opportunities. This has been announced as a public introductory lecture, in the hope that, at a time when the professional attainments of architects are about to become the subject of special examinations, what is here said may, perhaps, travel a little beyond the walls of this class-room, and so may help to draw public attention to the fact that University College has taken in the past, and is prepared to take in the future, her full share in the education of those who are intending to exercise the profession of architects. Before passing on to the consideration of the work to be done in the future, the past history of these classes, and the names associated with them, claim our attention. You probably all know that this is not a course of instruction now to be begun, but one which has been carried on for many years, and round which not a few associations have gathered. No small part of my responsibility to-day is due to the distinguished bearing, ability, and success of the professors whom I have the honour to succeed in this chair.

Professor Donaldson, happily still living to enjoy an honoured retirement, is the father of the profession of architects in England. As the founder of the Institute, and in a hundred other ways, he has conferred benefits of the greatest importance upon architects as a body. As the first Professor of Architecture in this College, he has been most helpful to very many living architects of eminence, who have studied under him here. I had myself the great advantage of attending Professor Donaldson's lectures as a student, and I am glad to take this opportunity of saying how largely I feel indebted to him. The vast stores of his learning were poured out before his classes ungrudgingly. The kindness of his manner made us all feel at home with him; and the unfeigned interest which he took in our progress was the very thing to rouse and stimulate our own love of our work. We all know something of the researches in Greece, and the studies in Italy, which will identify the name of Donaldson with the pursuit of Classic architecture as long as the literature of that architecture continues to exist, and, partly on that account, but far more in consequence of his personal qualities, Professor Donaldson was respected, beloved, and valued by us all, as no man ever can be whose attainments and whose character are not both of the highest kind. He established a comprehensive course of instruction in the art and in the science of architecture, and what he so started remains in the main the rule of study here to this day. I should not like to pass without mention the vast labour undergone by him in providing diagrams to illustrate his lectures, and the high artistic merit of the greater part of those diagrams. As specimens of architectural drawing and tinting, these sheets (the chief of them being the work of his own hands) were calculated to exercise the best possible influence on the students. They placed before us good examples drawn in a singularly artistic manner. Nor did the Professor's services to his pupils stop at placing illustrations before us. With rare liberality he put them into our very hands, lending them to us for private study at our own homes. There is much more which I should like to say were this the proper occasion, but I will only add (what is, perhaps, the highest tribute that I can offer) that there were few of the students in Donaldson's classes who did not at the close of the session feel that they had not only attended a learned Professor, but had made a valued friend.

When Professor Donaldson retired, his duties devolved upon my immediate predecessor, Professor Hayter Lewis. I cannot speak of his work from the same stand-point which my memory of student days affords me in regard to Professor Donaldson; yet, having had the honour to be long associated with him in work elsewhere, and more recently to act as his substitute here, I feel that I am, perhaps, as competent as any one not his pupil can possibly be to appreciate at their true value Professor Hayter Lewis's services in this chair. Public-spirited, like his predecessor, Professor Hayter Lewis has been a signal benefactor to the body of architects at large; and the establisment of voluntary examinations open to students of architecture was only one, though probably the most important, of the measures which he has been instrumental in forwarding. In this college he has laboured assiduously and with signal success, bringing to the work a wide store of learning, a singularly accurate, orderly, well-regulated method of procedure, and the attainments of a highly-cultured artist, student, scholar, and traveller. He has largely added to the already ample series of illustrations which, by the kindness of Professor Donaldson, have been allowed to be used, and he has most liberally permitted his drawings also to remain here for your benefit. It is a matter for sincere regret that Professor Lewis should have felt it necessary to retire from a post the duties of which, had his health permitted, he might have discharged for many years with the greatest possible advantage to students of architecture and to this college.

I cannot but feel how serious is the responsibility cast upon me in succeeding to men of such powers and such attainments, and I can only say that I will do my very best to keep near the high standard reached hitherto in the work of these classes. I should be the first to admit that I am in many respects unequal to my predecessors; yet I ought fairly to add that unless I had felt that I could in some degree do justice to the post I would not have sought it or accepted it. As far as I know my own powers and attainments, I will so shape the course of study here that students shall have the best which it is in my power to give, and so far as I feel my own proper line to differ from that natural to those who have gone before me, to that extent and no further, do I propose to modify the method or system of teaching which I shall pursue. As to the subject-matter of the lectures, that in the main must continue what it was under my predecessors; but with the addition, as a permanent branch of the subject, of the course of lectures on Professional Practice, which, with the concurrence of Professor Lewis, I introduced as an experiment two sessions ago; for the attendance upon these has fully justified my belief that the subject was one on which lectures would be felt to be acceptable. The classes, I need hardly say, are intended especially for young men who are being educated for the profession of architects, and they have been and will be carried on with a view to being made as useful as possible to students of this description. The courses, in whole or in

part, have, however, been found useful by persons who are preparing for or following kindred pursuits, as civil engineers, surveyors, builders, and others. The classes are in no case intended to supersede the training obtained by being articled or apprenticed, but they will aid the pupil, partly by enabling him to make a better use than he otherwise could of the opportunities presented to him by his pupilage, and partly by giving him information and rousing in him trains of thought which would not easily reach him in the routine of an architect's office.

It appears to me very unlikely that pupilage will ever cease to be desirable. I once, I confess, thought differently, and imagined that some well-arranged system of class teaching might in time come to supersede it; but I am becoming convinced that nothing but practice can well teach so very practical an art as that of the architect. But even in the offices which afford the most favourable opportunities, the pupil will be unable to learn all that he ought to acquire; and this deficiency must in some way be made up, or the young architect will be but inadequately equipped for his work. It is here that classes such as those which open this week come in most advantageously. They provide instruction such as the office in no instance can furnish. It is, moreover, not only the subjects taught, but the manner of teaching, which renders a class a valuable auxiliary, especially to a beginner. This consideration is too often overlooked, but it is one well worth attention. The instruction given in class is of the same kind as that to which the young student has been indebted for almost all that he has learned in school or college. He is used to it, and he knows, or ought to know, how to learn from it.

When a young man passes from a condition of life in which all his subjects of study have been taught him by qualified and appointed instructors, in which his time has been divided up for him into definite lectures, and in which his work is daily examined and his progress tested, and takes up the position of a junior in an office, who has to learn what he can, as best he may, from such share of the office work as his superior is able to entrust to his hands, the change is a great wrench. To some natures, of course, the altered circumstances act as a stimulus, and the new pupil begins rapidly to acquire knowledge; but this does not always,—or, in my opinion, often,—occur. It is seldom, I fear, the case that much good is done till some months more or less have been spent; and unhappily it sometimes occurs that the youth does not find his feet for years, if at all, and that invaluable time is lost. If for no other reason, it would be worth while for pupils to attend some kind of class, so as to keep up the old habit of study; and when a very arduous profession, requiring a great deal of technical information, has to be mastered, it is better that such class should be one which will contribute towards this end if possible, than one not bearing immediately upon professional training.

To put the matter shortly, the pupil best sees and learns practice in the office where he is articled. He will best learn the principles which underlie that practice in some such college as this.

But it may be felt and urged that there are other ways of supplementing the practical training acquired in the office; and that it is not necessary to attend classes in order to acquire theoretical and historical information about architecture. Construction is no new science; architecture is not an art of modern creation, and many excellent standard books are accessible. The money payable as college fees would go far to procure a fair library of works of reference, and the time spent over the classes would suffice to master the contents of the volumes. I do not deny that this is so, and that the student able and willing to read, especially if he can read French, German, and Italian with facility, has access to the instruction of teachers far more profound in their knowledge of their various subjects than I can ever hope to become; and yet there can be little doubt that, especially in London, with its many amusements and many claims upon time, there is a poor chance of that steady, regular attention being given to a course of reading which is required to render it thoroughly useful. Many students, especially in the country, have only the resource of reading to supplement their office-work, and well it is for them that books, and good ones, are accessible; but I have no kind of hesitation in saying that a year's attendance at classes will fix in the mind far more information than a year's reading. There is an impressiveness about the living voice which is wanting to print and paper; there is a stimulus in the presence and rivalry of class mates; the regular recurrence of the lecture evenings is of great advantage in securing that some time each week shall be devoted to study; there is, in short, at a college more inducement to close attention and careful note-taking than under the ordinary circumstances of study from books without an instructor; and the illustrations which the liberality of the past Professors have placed at your disposal, and those which I may be able to furnish, together with the specimens of materials, are of more value than most book illustrations. To those, then, who are fairly able to attend, I can, therefore, honestly recommend the direct personal teaching given in this classroom and at King's College, and the combination of teaching and mutual instruction so successfully carried on by the members of the Architectural Association, as calculated to aid their progress very materially.

In many classes in this and every other college, the subjects of instruction are chosen and arranged so as to prepare the student for passing a certain examination. The subjects for the first B.A. and the second B.A., and the B.Sc. examinations, are provided for, and the examinations alluded to in various parts of the college programmes. This college, it is true, is not an establishment intended for preparing young men for examinations; but it must not be forgotten that both the examinations and the programmes of the classes have been carefully arranged to provide what experience seems to point out as necessary to a thorough education, special or general. More than this, there are now so many walks in life to which the passing an examination of some sort, or a whole series of them, forms the entrance, that it would be wrong were the subjects taught in the classes here not to a large extent made to correspond with the subjects required for examinations.

For the first time we now have an examination established which every architect who intends to take a position such as membership of the Institute confers, must pass; and though I do not wish these classes to be considered as being henceforth devoted solely, or even chiefly, to preparing pupils for that examination, as conducted by the Institute of Architects, it would be idle to ignore what has taken place, the more so that I myself have given up a large amount of time and trouble to the organisation of the examination, and through many years past to the promotion of the voluntary examination which preceded it.

I shall have shortly an opportunity of discussing the subject in a paper to be read before the Architectural Association, so I will not enlarge upon it here. I must, however, point out that the programme of the examination issued by the Institute may be taken as embodying the minimum of attainment and skill which, in the opinion of the council of that body, and of a large committee of men of experience who advised the council, should be possessed by every architect at the outset of his professional career. It will consequently, I think, be useful to examine this programme, and to point out how much of its requirements can be supplied by information to be learned here, and how much is left to be obtained from the practical education which you must gain in the office, on the scaffold, from your sketching-tours, and in your own studies. The obligatory preliminary work consists of a set of plans with a perspective drawing, a sheet of details, and an ornament. This is, of course, intended to elicit practical skill in architecture generally and in handling drawing materials and making drawings. That skill must, of course, be gained elsewhere, but I hope that the work would be indirectly benefited by what is learned here. Work done as a student, such, for example, as sketches from the diagrams, notes, or essays, may be also submitted, at the option of a candidate. The first subject for examination is the history of architecture, taking a general view of a wide field, and an examination in some detail of a single division of the subject. Our Art course of lectures here supplies the information needed for this paper, and arrangements (which I shall explain presently) will be made in order to enable the students to bestow special attention on one special subject each year, so as to correspond more exactly with the course of examination. The second subject of examination is one intended to show that the student has mastered some one style sufficiently to give him a command over its forms and features, so that he could use it on a building without committing gross errors. This subject is largely a test of practice and drawing and private study, but the classes will materially assist the student in his preparation for this paper, especially if he select the special subject of study alluded to above. The third subject is materials, construction, and sanitary science; and our Construction course covers the whole of these subjects as indicated in the Institute programme. I need hardly add, I hope, that practical as well as theoretical acquaintance with these subjects will be necessary in order to satisfy practical examiners, and must be sought on the works to which the student has access. The fourth subject of examination is planning; and here practice will be of more use than teaching. I do, however, propose to deal with planning, as far as it can be usefully considered in the class-room, in my Professional Practice course. The fifth subject,—specifications and estimates,—is one which is constantly kept in view in the construction course, but on which direct instruction is given in the practice course. Here, again, practice elsewhere must be relied on to supplement the class-room work. Finally, professional practice to a limited extent forms the sixth and last subject of the programme. This is fully dealt with in the course devoted to the subject. From this hasty view it will be seen that as much as the class-room can contribute to the student's preparation for passing this examination will be provided in our course of study here.

Another examination, that to be passed by candidates for the post of district surveyor, has recently been remodelled and rendered more searching than before. Here, again, practice and theory will both be tested; but most of the subjects which are likely to be touched upon form part of our construction course, in which materials, construction, and ruinous structures are all dealt with; and of our practice course, which includes lectures on the Building Act.

I need only, I think, add that the examinations at the close of these courses, with possibly some intermediate examination, will afford the students a means of estimating their chances of success in these more important examinations, and good practice in answering questions on these subjects.

You shall now hear exactly what is done and is to be done in the classes. They include three courses, denoted A, B, and C, and treating respectively of art, science, and professional work.

The art-class,—Class A,—approaches architecture as a fine art from the side of history, and necessarily so. You can hardly in any other way understand the subject. The design of every great group of buildings,—nay, to a greater or less extent, of every single building of importance,—was largely influenced by the design of buildings previously existing, and, in its turn, exercised an influence on what was built afterwards. An English church, for example, is planned in the manner familiar to you all, with a nave and aisles, mainly in consequence of that arrangement having been in use near the Christian era in Rome for courts of justice. In short, there is little about a building that cannot be better understood by knowing its history than in any other way, and there is much which is quite unintelligible without such knowledge. Course A, as given by my learned predecessors, has embraced that series of architectural styles which stand in some sort of relationship to the architecture of modern Europe. That is to say, the ancient architecture of Egypt, Assyria, Persia, Greece, Etruria, and Rome, and architecture since the Christian era,—of the styles known as Basilican, Byzantine, Romanesque, Saracenic, Gothic, and Renaissance. This is an immense field. It certainly shuts out the vast and extremely interesting architecture of India and Japan, but with this exception it leaves very little of interest unnoticed. Professor Donaldson used, I think, to bestow most of his attention on the Classic styles of the ancient world,—the field where his laurels as an investigator and a discoverer were won. Professor Hayter Lewis, if I mistake not, leant more in the direction of Early Christian and Saracenic art,—subjects to the study of which he has devoted much time abroad as well as at home. Possibly my own inclinations, and my studies on the Continent, may induce me to devote a rather larger proportion of attention to

Renaissance work; but I shall endeavour to follow my predecessors in giving fair and honest attention, so far as time will permit, to each part of the field in turn.

It is, of course, not possible, in dealing with so large a subject, to treat much of it in great detail, but though a comprehensive view is sufficient for the ordinary purposes of the student, I am convinced that he ought to be taught some one style more thoroughly, partly with a view of putting him in the way of studying other styles for himself with equal thoroughness, and partly also in order to prepare such students as intend to offer themselves for examination at the Institute. I propose accordingly, as an experiment, to expand one portion of the course, and treat one subject at greater length, or at least in more minute detail, than the rest, endeavouring to pursue it far enough to make the class somewhat familiar with the mouldings, ornaments, and more minute details of the style, as well as with the general architectural forms and the leading features of the buildings.*

DECREASE IN THE VALUE OF CITY OFFICE PROPERTY.

The great extent to which the erection of commercial buildings and offices has for some time past been carried on in the City appears to have had a prejudicial effect on the annual value of this class of property. At the late half-yearly meeting of the shareholders in the City Offices Company, the Chairman, Sir Thomas Dakin, said they had lost several valuable tenancies, and though they saw their way to re-let the premises, the competition had been of such a nature through the many new buildings which had been erected in the neighbourhood, that they had been obliged in several cases to re-let the vacated offices at a smaller rent than they received before. They had, however, acted on the principle of keeping their offices filled as far as possible, but in times like the present to let them uniformly for short periods. The unlet portion of their property had been reduced from 6,575*l.* on the 31st of December last, to 4,362*l.* at the close of the half-year, and therefore they had made a very substantial increase in the letting of their property. The Chairman added that an important incident of the half-year had been the taking of their Tower-street property by the Metropolitan and District Railway Companies for the completion of the Inner Circle line. The property stood in their books at 35,785*l.*, and they would obtain 35,552*l.* for it. The rental of the property was from 1,500*l.* to 1,550*l.* a year, and the terms upon which the companies had purchased it were twenty years' purchase on the net rental, and 10 per cent. for the compulsory sale.

LIGHTING UP THE ST. GOTTHARD TUNNEL.

The mode of lighting the St. Gotthard Tunnel has been the theme of much discussion, and, naturally, the electric light finds most favour. Two systems have been proposed as practicable. According to one plan, the compressed air-pipes are to supply the motive power for producing the electric light. About forty lights, each of 1,200 candle-power would be sufficient to light the tunnel. The other scheme advocates the employment of movable lights. For this purpose specially-constructed locomotives could be used, which are to take in at each end of the tunnel a sufficient supply of compressed air to pull the train through it and furnish the motive power for two electro-motors. The light produced by them is thrown by reflectors both in front and rear of the train, and thus completely and efficiently light up that portion of the tunnel through which the train is proceeding.

Stone for Truro Cathedral.—The general committee have resolved that Carnsew (Cornish) granite should be used for the plain ashlar work of the outer walls; "Box ground" Bath stone for the outside "dressed" work, or, in the discretion of the architect, "Doulting"; that the bulk of the interior plain work should be of St. Stephen's (Cornish) granite, and the interior dressed work of Bath or other stone, at the discretion of the architect.

* To be continued.

THE NEW UNIVERSITY COLLEGE BUILDINGS, NOTTINGHAM.
